Subject: IPAA Supplemental Materials on the Subpart OOOOa Reconsideration
Attachments: Independent Producer Response to Comments 06-17-2019.pdf; Independent Producers' Comments on 2018 Proposed Revisions to Subpart OOOOa.pdf

Clint,

IPAA has submitted some additional materials to Subpart OOOOa docket regarding some specific issues related to low production wells and the alternative methods to measure emissions. These comments are largely written to address allegations made by the Joint Environmentalist Coalition. I have attached those comments along with the original IPAA comments submitted in December 2018.

We have met with the technical staff in North Carolina to discuss these issues. I would like to arrange a meeting with you and other EPA policy staff in Washington. I'd like to suggest a possible meeting during the weeks of July 8 or 15 when your schedule permits.

Thanks,

Lee Fuller

Response/Supplemental Comments

The Honorable Andrew Wheeler, Administrator
US Environmental Protection Agency
1200 Pennsylvania Avenue, N.W.
Washington, DC 20460

VIA E-MAIL AND E-FILING

June 17, 2019

Re: Environmental Protection Agency's Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources Reconsideration at 83 Federal Register 52056 (October 15, 2018) – Supplemental Comments

Docket ID No. EPA-HQ-OAR-2017-0483

Dear Administrator Wheeler:

The following Supplemental Comments are submitted on the above-referenced proposed Reconsideration Rulemaking ("Reconsideration Rulemaking") on behalf of the following national and state trade associations: the Independent Petroleum Association of America ("IPAA"), American Exploration & Production Council ("AXPC"), Domestic Energy Producers Alliance ("DEPA"), Eastern Kansas Oil & Gas Association ("EKOGA"), Illinois Oil & Gas Association ("IOGA"), Independent Oil and Gas Association of West Virginia, Inc. ("IOGA-WV"), Indiana Oil and Gas Association ("INOGA"), International Association of Drilling Contractors ("IADC"), Kansas Independent Oil & Gas Association ("KIOGA"), Kentucky Oil & Gas Association ("KOGA"), Michigan Oil and Gas Association ("MOGA"), National Stripper Well Association ("NSWA"), North Dakota Petroleum Council ("NDPC"), Ohio Oil and Gas Association ("OOGA"), Oklahoma Independent Petroleum Association ("OIPA"), Pennsylvania Independent Oil & Gas Association ("PIOGA"), Texas Alliance of Energy Producers ("Texas Alliance"), Texas Independent Producers & Royalty Owners Association ("TIPRO"), and West Virginia Oil and Natural Gas Association ("WVONGA") (collectively, "Independent Producers"). The Independent Producers have participated individually or through the Independent Producers in most, if not all, of the rulemakings and associated litigation since the Environmental Protection Agency ("EPA" or "Agency") proposed to revise the New Source Performance Standards ("NSPS") for the Oil and Natural Gas Sector in August 2011. 76 Fed. Reg. 52,738 (Aug. 23, 2011).¹ While many of the Independent Producers represent companies that engage in large volume hydraulic fracturing with horizontal legs, often referred to as unconventional drilling, a significant portion of their membership is also comprised of smaller, family run operations that engage in some form of hydraulic fracturing, involving vertical wells without horizontal legs, referred to as conventional oil or natural gas wells. Many

¹ As EPA has opened a new docket for the Reconsideration Rulemaking, the Independent Producers incorporate by reference their Comments on the previous rulemakings associated with 40 C.F.R. Part 60, Subpart OOOO and Subpart OOOOa, including but not limited to the following documents: EPA-HQ-OAR-2010-0505-4216, EPA-HQ-OAR-2010-0505-4626, EPA-HQ-OAR-2010-0505-4752, EPA-HQ-OAR-2010-0505-4767, EPA-HQ-OAR-2010-0505-7001, EPA-HQ-OAR-2010-0505-7685, and EPA-HQ-OAR-2010-0505-12337

of the individual members constitute small businesses under the Small Business Regulatory Enforcement Fairness Act of 1996.

These supplemental comments are filed by the Independent Producers in response to initial comments and supplemental comments filed by others, including some that directly address the Independent Producers initial comments (filed December 17, 2018).

Framing the Issues

The Independent Producers comments addressed several key issues where the proposed Reconsideration Rulemaking adversely affect American oil and natural gas production. These include the following that were directly addressed in comments by others:

1. Alternative Means of Emission Limitation (AMEL) for state equivalency to the required leak detection and repair (LDAR) provisions for fugitive emissions; and,
2. The treatment of low production wells

To put these supplemental comments in context, following are synopses of the initial Independent Producers comments on these issues.

AMEL for emerging technology and state equivalency to the required leak detection and repair (LDAR) provisions for fugitive emissions

The Independent Producers support the options in the Proposed Revisions to use modeling, to test technologies in a controlled test environment, and to allow manufactures/vendors to apply for approvals. EPA should allow for basin-wide approvals of emerging technology for use in complying with the LDAR requirements in the rule. EPA can establish clear and consistent parameters under which a technology will be able to detect methane emissions and site specific variables can be addressed in conditions required for the use of the technology. Basin-wide data is necessary to determine equivalency and receive approval per CAA 111(h); basin-wide surveys that can identify potential fat-tail emission sources faster and per the EPA, higher mass emission reductions from large leaks, found earlier, are offset by some degree by smaller leaks which go undetected. Common sense dictates basin-level approval; the 111(h) notice and comment process required to achieve approval is very onerous and not feasible to do for every single well site. CAA Sec. 111(h)(3) does not constrain basin-wide approvals.

Per cooperative federalism, EPA should recognize the approved state programs as wholly equivalent to 40 C.F.R. Part 60, Subpart OOOO's ("Subpart OOOO") LDAR program and fully delegate the implementation of the LDAR monitoring provisions to these respective states. Alternatively, EPA could require the fugitive emissions component definition from Subpart OOOOa to be used when following an alternative approved state program but EPA should not require a duplicative administrative burden; to do so would be an undue burden with no corresponding environmental benefit.

The treatment of low production wells

Subpart OOOOa in the context of its application to oil and natural gas production emissions expands on a regulatory network that includes Subpart OOOO. Subpart OOOO applies to the significantly more substantial emissions sources. However, in their entirety, these oil and natural gas production sources currently account for approximately 1.2 percent of the US Greenhouse Gas Inventory (GHGI).

There are approximately one million oil and natural gas wells in the United States. Within this category of sources are low production oil and natural gas wells (wells producing 15 b/d or less or 90 mcfd or less).

There are approximately 770,000 low production oil and natural gas wells in the United States. These wells account for about 10 percent of US oil production and 12.5 percent of US natural gas production. If these wells emit methane comparable to their production volumes, they would account for an amount less than 0.15 percent of the total GHGI.

While Subpart OOOOa addresses new and modified sources, because it applies to a non-criteria, non-hazardous chemical – methane – it will trigger a nationwide existing source regulatory requirement for oil and natural gas production facilities – Section 111(d). Section 111(d) was squeezed into the Clean Air Act to address what can only be understood as a small number of pollutants that would not fall into the larger categories – and correspondingly – to a small number of sources. Section 111(d) was never envisioned as a regulatory framework for a source category with a million facilities.

EPA's creation of an expensive, burdensome and ineffective Optical Gas Imaging (OGI) LDAR fugitive emissions program for low production wells in Subpart OOOOa threatens the economic viability of existing low production wells without a sound basis or reasonable expectations of emissions reductions. While emissions information has been gathered from oil and natural gas production operations, none of these efforts was designed to address low production wells. Rather, low production well data has been culled from the larger data pool. The vast majority of data collected does not distinguish fugitive emissions from permitted emissions. Similarly, when EPA has turned to alternative approaches of using component counts and emissions factors, it has relied on data from an extremely small sample of low production wells and from emissions factors based on a 25-year-old study. Neither that study nor the more recent emissions studies were designed for the purpose of crafting regulations. The Independent Producers believe this information is insufficient to impose requirements that disproportionately affect low production wells.

The Department of Energy (DOE) has initiated a study of low production well emissions that should be finished before low production well regulations are required and could be used to develop a sound low production well regulatory framework if one is necessary.

These supplemental comments will address comments filed by the Joint Environmental Coalition (JEC) on the initial proposed revisions to Subpart OOOOa as well as their supplemental comments submitted by February 21, 2019. The JEC members are advocates for the termination of American fossil energy production. The JEC comments must be viewed in the context that their underlying objective is to produce EPA actions that prevent new American oil and natural gas production and terminate existing American oil and natural gas production. These supplemental comments address comments by the JEC seeking to stop American production that are inaccurate or address issues of particular concern to the Independent Producers.

The organization of these comments will be:

1. A review of the JEC basis for its positions
2. Responses to the JEC Supplemental Filing – February 21, 2019 – Criticisms of Industry Comments with a principal focus on the low production well issues raised

3. Responses to the JEC initial Comments with a principal focus on low production well issues; and,
4. A response to JEC issues related to AMEL for state equivalency.

Joint Environmental Coalition Basis for Its Positions

At the center of the comments submitted by the JEC are a series of studies and reports that present its perspectives on methane emissions related to the production of American natural gas and oil. Each of these items present highly inaccurate and questionable assessments and present them with strident evangelical certainty that vastly overstates their accuracy and value. To place the JEC arguments and criticisms in context, it is useful to review documents cited in their comments.

1. Economic Analysis of Methane Emission Reduction Opportunities in the U.S. Onshore Oil and Natural Gas Industries (ICF Study)

This report funded by EDF created an array of cost effectiveness calculations in \$/mcf based on a series of critical assumptions. Since its completion, EDF and other members of the JEC have touted it as demonstrating that methane emissions can be reduced with technologies that only cost cents per day. While aggregating all of the cost effective technologies with the cost ineffective technologies might produce such a result, individual technology options do not. Equally significant are the EDF assumptions of the value of natural gas in calculating the benefits of regulations and the efficiency of the requirements. These are particularly important in the context of the fugitive emissions proposals.

EDF concludes that a quarterly fugitive emissions program for natural gas wells would recover 264 mcf/y using a 60 percent recovery rate on emissions of 440 mcf/y and have a cost burden of \$7.60/mcf without recovery benefits and \$2.52/mcf with recovery.

Putting this evaluation in some context changes the perspective. First, looking at the emissions and recovery quantities on a daily basis shows them to be 0.72 mcfd and 1.2 mcfd, respectively. These are small volumes for even the average well. EDF does not indicate the average production rate for the wells it assumes for the average emissions, but the average US natural gas well produces about 127 mcfd. Therefore, the approximate emissions rate would be about 1.0 percent. Nor does EDF appear to distinguish sources of emissions in its fugitive discussion. For example, it does not discuss the share of emissions coming from equipment and those coming from storage tanks that have permitted releases. Since an LDAR program would not apply to these allowable emissions, the efficiency/cost estimates must be questioned.

A second key point of the analysis relates to the value of natural gas where EDF assumes a price of \$4.00/mcf. Producers have not received such a price for a long time and do not foresee such a price for many years. As the Independent Producers submitted in its original comments, the recent price for natural gas has been nearer \$2.22/mcf of which the producer receives approximately \$1.67/mcf. If this price replaces the EDF assumptions, the value of the recovered natural gas would drop from \$1360 to \$440 annually. Correspondingly, the cost effectiveness would change in the net case from \$2.52/mcf to \$5.48/mcf.

A third point relates to the scope of fugitive leaks of the Leak Detection and Repair (LDAR) program. A study done by Carbon Limits (described below) concluded that fugitive leak emissions at well sites accounted for 17 percent of the total site emissions. Using this assessment of the 440 mcf/y of site emissions, only 75 mcf/y would be addressed by the LDAR

program. And using the generous assumption of a 60 percent recovery, 45 mcf/y (0.12 mcf/d) would be recovered. This would result in \$75 in recovered value. The cost effectiveness would then become \$44.58/mcf in the gross case and \$42.91/mcf in the net case

More critically, the issue of larger significance here is the application of an LDAR program to low production wells. These wells average about 24 mcf/d rather than 127 mcf/d. Moreover, in some significant natural gas producing states the average low production natural gas well is much less; in Pennsylvania, for example, it is 6.1 mcf/d. Using the same ratio of emissions to production for the average national well would yield low production emissions rates of 0.24 mcf/d nationally and 0.06 mcf/d for Pennsylvania. On this basis the potential recovery would be 9 mcf/y for the national average low production well and 2.2 mcf/y for the Pennsylvania well. The gross and net cost effectiveness values would be \$222.89/mcf and \$221.22/mcf for the national wells and \$911.81/mcf and \$910.15/mcf for the Pennsylvania wells, respectively. Setting aside that most of the likely emissions would be from permitted storage tank vents, these assessments argue that the Optical Gas Imaging OGI LDAR approach is not cost effective.

2. Quantifying Cost-effectiveness of Systematic Leak Detection and Repair Programs Using Infrared Cameras (Carbon Limits)

This report was prepared for the Clean Air Task Force by Carbon Limits. It is designed to assess LDAR programs using infrared cameras for various components of the natural gas value chain. Environmentalists like to reference it because of its general conclusions that these LDAR programs can be cost effective. But, a closer look reveals a number of key points that demonstrate a very different result particularly in the context of low production wells.

First, like other analyses this report is based on recovering methane at a natural gas price of \$4.00/mcf. While it does develop an effect case if natural gas were priced at \$3.00/mcf, it does not approach an analysis at the \$1.67/mcf prices that have characterized the recent prices that producers receive.

Second, as mentioned above, it concludes that natural gas well leaks that would be the subject of an LDAR program represent only 17 percent of the methane emissions from well sites.

Third, the report develops Net Present Value (NPV) determinations for each industry segment that it evaluates — well sites and well batteries, gas processing plants and compressor stations in gas transmission, and gas gathering systems. For well sites and well batteries, the Carbon Limits study concludes that infrared camera based LDAR programs are not cost effective at 85 percent of these sites — a percentage that exceeds the share of natural gas production facilities that are low production wells. Moreover, since this assessment is based on \$4.00/mcf natural gas, it would thereby mean that such an LDAR program would be not be cost effective for an even greater percentage.

3. Waste Not: Common Sense Ways to Reduce Methane Pollution from the Oil and Natural Gas Industry (Waste Not)

This report was prepared by the Clean Air Task Force, the Natural Resources Defense Council and the Sierra Club. It essentially presents information from other sources arguing for a methane-based expansion of Subpart OOOO in order to expand regulation to existing sources. Its information is largely restatements of the information from the ICF and Carbon Limits reports described previously and therefore suffers from the same limitations, including the use of a natural gas value of \$4/mcf. Moreover, since it predates Subpart OOOOa, much of its emissions

reduction calculations apply to the broad array of possible regulations and are not limited to those addressed in the Subpart OOOOa reconsideration. The only intriguing element of its recommendations is the realization that a fugitive emissions program needs to differentiate its requirements based on the production volumes of the facility.

4. *Toward a Functional Definition of Methane Super-Emitters: Application to Natural Gas Production Sites (Super-Emitters)*

This study was commissioned by the EDF and clearly demonstrates the outcome-based purpose of the effort. It represents an effort to carefully cull data from other efforts and recast it as a new analysis to create the impression that low production wells are “super-emitters”. It manipulates data to twist reality for the purpose of convincing EPA and others to regulate low production wells. The Independent Producers have addressed the abusive structure of this study in earlier comments. Those statements are restated herein:

Manipulating Data to Create the Illusion That Low Producing Wells Are “Super-Emitters”

This document addresses data manipulation issues in the environmentalist study submitted to the rulemaking proposal for Subpart OOOOa to distort the role of low producing wells regarding methane emissions. This study was then characterized as the basis for removing the low producing well exclusion for the Subpart OOOOa fugitive emissions program initially proposed by the Environmental Protection Agency (EPA).

Background

Initially, it is important to understand that this study used data from a number of different studies to create its arguments. All of the underlying studies generated their data by driving vehicles with samplers downwind of production sites, hunting for methane plumes. None of them used samples taken on the production site. This creates two issues. First, it measures everything emitted at the site – fugitive emissions and permitted vents. Second, the data are collected over minutes – maybe over an hour – but not over a day. The data in the study are presented as if they were daily emissions but the studies merely scale up hourly estimates. Consequently, an emission that might occur for several hours, but not the full day, would be overstated.

Before turning further to describe the submitted study, it is useful to look at the same data using a direct graph of emissions. In this graph, marginal wells are those with production volumes of 90 mcf/d or less.

This graph is consistent with information from other studies showing that a small portion of wells have an emission profile for some reason with high emissions and most wells have really low emissions. Importantly, it also clearly shows that marginal wells – low producing wells in the context of the regulation – have far smaller emissions. But, since this graph is using the same data as the study, it could also be overstating emissions because of scaling short term emissions to a daily amount.

With this background, turning to the presentation of the same material in the study demonstrates how it was manipulated. Below is the graphic used to present the data. It would suggest that the worst emitting operations – the “super-emitters” –

are the smallest wells (the orange line and the blue line, circled in green). Having directly plotted this data, the obvious issue is how such a result can occur.

It is a busy and confusing graph – it's intended to be. The study uses data analysis tricks to create the appearance that marginal wells are “super-emitters”.

First, it shows emissions as a percentage of production rather than actual emissions. Thus, one mcf emitted out of ten mcf produced is 10 percent, but 50 mcf emitted out of 1000 mcf produced is 5 percent. As a result, it skews the perception of the data to imply that low producing wells are large emitters when they are not.

Second, its production volumes are really sales volumes, not the amount extracted from the wellhead. Consequently, a “proportional loss rate” of 50 percent would be the calculated loss divided by the volume sold. If the percentage of loss were calculated based on extracted volumes, the 50 percent “proportional loss rate” would drop to 33 percent because the loss would be added to the sales volume to obtain the extracted volume.

Third, it only shows data from the 70th percentile of information. This excludes all of the virtually zero emissions that dominate the data.

Fourth, it uses a logarithmic scale to present the data. One of the reasons to use logarithmic scales is to flatten curves to make them look more like straight lines.

5. *Aerial Surveys of Elevated Hydrocarbon Emissions from Oil and Gas Production Sites (Lyon 2016)*

This report was completed for the Environmental Defense Fund and utilizes aerial data collection techniques to develop information. The data for the report were taken from June through October 2014. Consequently, of the 8220 well pads that were sampled, only 1574 would have been subject to the requirements of Subpart OOOO which became effective for new facilities after August 2011.

The study provides some useful insights. For example, it states:

Tank hatches and tank vents were the most common source type of detected emissions, comprising 92% of observed sources. The remaining 8% of detected emission sources were dehydrators, separators, trucks unloading oil from tanks, and unlit or malfunctioning flares.

Of these, 184 would have been under the Subpart OOOO requirements. The remainder would have been allowed to have vented emissions without federal requirements for vapor recovery. In addition to vented emissions, tanks can have emissions from open hatches or corrupted seals.

The report also observes that its data may not reflect annual emissions information stating:

Since our observations were limited to summer/fall and daylight hours, we were not able to assess how annual average prevalence may be affected by seasonal or diurnal trends such as higher tank breathing losses during warmer conditions.

This is a plausible issue since temperature can affect breathing losses.

Additionally, the validity of aerial surveys is an issue that has been questioned because – like other forms of data collection that is both based on measurements of sites from offsite and on measurements that are taken for a limited period of time and then extrapolated to daily or annual emissions – the lack of information on site operational conditions can result in inaccurate assessments. This issue has been addressed in a study published in 2018, *Temporal variability largely explains top-down/bottom-up difference in methane emission estimates from a natural gas production region*, which makes the following observation:

This study spatially and temporally aligns top-down and bottom-up methane emission estimates for a natural gas production basin, using multiscale emission measurements and detailed activity data reporting. We show that episodic venting from manual liquid unloadings, which occur at a small fraction of natural gas well pads, drives a factor-of-two temporal variation in the basin-scale emission rate of a US dry shale gas play. The midafternoon peak emission rate aligns with the sampling time of all regional aircraft emission studies, which target well-mixed boundary layer conditions present in the afternoon. A mechanistic understanding of emission estimates derived from various methods is critical for unbiased emission verification and effective greenhouse gas emission mitigation. Our results demonstrate that direct comparison of emission estimates from methods covering widely different timescales can be misleading.

Like other reports, this one was not structured to specifically address low production wells but it includes information that presents some useful insights regarding the low production wells it sampled. Of the 8220 well pads sampled, 4195 were low production wells (15 BOE/day or less), averaging 4.1 BOE/day. Of these 4195 low production wells, 57 had measurable emissions (1.3 percent). Of these, 37 had tank vent emissions, 8 had tank hatch emissions and 2 had both tank vent and hatch emissions. The remaining 10 (0.2 percent) had emissions from dehydrators, separators, trucks unloading oil from tanks, and unlit or malfunctioning flares. These emissions are not clarified regarding whether the emissions would be considered as fugitive or whether they are from allowable vents or normal operations (e.g., truck unloading). However, it does clearly call into question the benefits of an OGI based fugitive emission program to address the small percentage of low production wells that would be dealing with non-tank emissions.

6. *Methane Emissions from Conventional and Unconventional Natural Gas Production Sites in the Marcellus Shale Basin (Omara Marcellus 2016)*

This report includes information on both unconventional natural gas wells and conventional natural gas wells. For both types of wells remote sensing of emissions was undertaken and the facilities were examined using OGI, although most of the site examinations occurred without the participation of the facility operator. Among the report's conclusion is the following:

Based on our results, the estimated 2014 CH₄ leakage from all routinely producing NG well pad sites, as a fraction of statewide CH₄ production, was 1.0% in Pennsylvania ... and 3.0% in West Virginia The combined regional CH₄ emissions (1150 Gg, Table 1) represented approximately 1.4% ... of total Marcellus CH₄ production (i.e., production from all routinely producing UNG and C_vNG sites in PA and WV combined) in 2014.

However, as Energy In Depth reports:

Importantly, Omara et al. is actually part of a larger federally-funded study (Presto et al.) that began in the Marcellus and eventually was expanded to include several basins across the country. That more recent and comprehensive study found that methane emission estimates for Pennsylvania and West Virginia were **actually 40 percent lower than those reported in Omara et al. — the study EDF bases its estimates off of** – due to “improved statistical power in the current study and methodological differences in the treatment of high emitting sites.”

Specifically, the more comprehensive 2017 study found,

“From the 511,000 O&G production sites, we estimated total U.S. onshore CH₄ emissions of 700,000 kg/h (or 6.1 million metric tons) in 2015. **These CH₄ emissions were equivalent to 1.43% of total CH₄ production in 2015**, or 1.6 kg/h/site.” (emphasis added)

...

The more comprehensive 2017 study also determined that 2015 methane emissions leakage rates in both the southwestern and northeastern parts of the state were **less than one percent of production**. This is significant for a variety of reasons, the biggest being that in order for natural gas to maintain its climate benefits methane leakage rates have to fall below 3.2 percent – and they are well below that rate in Pennsylvania. Importantly, the leakage rate estimate from the more recent and comprehensive 2017 study includes conventional sites (i.e. generally older equipment) and wells from the southwestern portion of the state where the gas is “wet,” meaning there are more natural gas liquids (NGLs) and thus more equipment on site (i.e. more opportunity for leaks). Still, the study found leakage rates **well below one percent of production**.

The report includes information from 19 conventional natural gas wells at 18 well pads, all of which are low production wells. The report suggests that emissions from these wells are proportionally higher than those from unconventional wells. Looking at the data more closely reveals some key facts.

First, it is important to recognize that this report suffers from the same limitations as most others. Its emissions information is taken remotely for limited times and cannot be converted accurately to either daily or annual emissions. Consequently, using the emissions determinations in the report should not be considered as accepting them as accurate. As the information above indicates, subsequent reports show far lower emissions rates.

Second, of the 19 conventional wells, onsite information related to an OGI survey is supplied for 18 of them. Of these 18, the average production rate was 13.08 mcf/d with calculated emissions of 1.22 mcf/d or 0.05 lbs/day. Translating this value to annual emissions, it would be 0.0092 tons/year.

Third, of the 18 wells, the OGI information shows that 11 of them were characterized by having storage tank emissions from vents or hatches. Their average production rate was 13.79 mcf/d with calculated emissions of 1.63 mcf/d or 0.067 lbs/day. Translating this value to annual emissions results in a calculated value of 0.012 tons/year (tpy).

Fourth, the current Volatile Organic Compound (VOC) Control Techniques Guidelines (CTG) document for oil and natural gas production facilities in ozone nonattainment areas recommends its Reasonably Available Control Technology (RACT) for storage vessels apply to storage vessels "...with a potential to emit (PTE) greater than or equal to 6 tpy VOC". The assumption in this report is that the methane content of the emitted vapor is 81 percent. Consequently, the annual emissions from the well sites with tanks would be approximately 0.019 tons/year. This is approximately 0.3 percent of the threshold for regulation in the current CTG.

Fifth, to put a final perspective on the implications of this report with regard to low production wells, according to EPA, "A typical passenger vehicle emits about 4.6 metric tons of carbon dioxide per year..." or 5.07 tons per year. Applying the Greenhouse Gas Inventory Global Warming Potential to the emissions calculations for these tank-based well sites, it would take about ten of them to equal one typical passenger vehicle.

Sixth, as the following graphic shows, oil and natural gas production facilities continue to reduce their methane emissions intensity in the Appalachian basin where this report obtained its information.

7. *Assessment of methane emissions from the U.S. oil and gas supply chain (Assessment of Studies)*

This EDF report was released with great fanfare during the 2018 World Gas Conference to create the appearance of new data showing methane emissions from the oil and natural gas industry value chain. The report purports to show that emissions are far higher than those reported in EPA GHGI. The JEC then refers to this report as a linchpin of its arguments for changes to the Subpart OOOOa proposal, particularly with regard to the fugitive emissions program with a special focus on low production wells. However, probing its details provides a far different perspective.

This report is not new data. Rather, it is a reconstruction of prior data from others' studies. For example, it regurgitates the same information in the Super-Emitters study and adds some additional material from others.

As a consequence, the report suffers from no certainty regarding the quality of its data by possibly exacerbating bias and inaccuracies through incompatible sampling and data collection methodologies. It accepts as accurate everything it receives and these data have glaring deficiencies.

The predominant data that is used for the bottom-up (BU) elements of the report are – as described frequently in these comments – facility measurements that can not distinguish between fugitive emissions and allowable emissions and that are remotely sampled. These failures are demonstrated in a number of statements in the report and its supplementary materials.

For example, one of the key issues in the use of remote sampling relates to interpreting the short-term information in the context of long-term emissions. In its supplementary material, the report states:

Measurement methods included the mobile flux plane technique ..., dual tracer flux approach ..., and OTM-33A, an inverse Gaussian method All three methods capture a snapshot of site-level emissions, with reported duration of individual plume captures of ~50 s ..., 30 s to a few minutes ... and 15-20 minutes

Consequently, using samples with time spans of 50 seconds, 30 seconds to a few minutes and 15-20 minutes, the report scales this information first to daily emissions and then to annual emissions. The approach generates an inherent and inappropriate characterization of emissions that cannot be considered accurate or valid. Further, the study presents no information regarding background levels inherent to various comingled land use activities and regional sources.

Similarly, the report makes a significant effort to try to discount this obvious emission estimating challenge by discounting the likelihood that short-term activities at the production sites could be the cause of its higher readings. However, since the researchers in their original data development chose not to work with production operations during data collection these assertions are a thinly disguised effort to rationalize the fundamental inability to understand the nature of the data. Consequently, rather than recognized that activity at production sites largely take place during daytime hours – activities such as liquids unloading, maintenance and liquid transfers – that could account for higher than normal emissions, the report attempts to argue the converse. In its supplementary materials it makes this statement:

In addition, there is no reason to expect daytime bias in the kinds of abnormal operating conditions that are thought to characterize high-emitting production (and gathering) sites, which operate continuously. In fact, it is plausible that abnormal emissions could actually be higher at night because they are less likely to be found and corrected in the absence of operators.

Yet, the very issue that arises in the use of daytime data is highlighted in a recent NOAA study and the point was addressed in the Independent Producers initial comments by inclusion of an EID analysis of this report and are restated later in this submission.

This Assessment of Studies report – faced with trying to justify its rationale for its higher emissions estimates – tries to dismiss anything that flies in the face of its biases. As it brings in its Top Down (TD) information the report includes this statement:

An extensive aerial infrared camera survey of ~8,000 production sites in seven U.S. O/NG basins found that ~4% of surveyed sites had one or more observable high emission-rate plumes ... (detection threshold of ~3-10 kg CH₄/h was 2-7 times higher than mean production site emissions estimated in this work). Emissions released from liquid storage tank hatches and vents represented 90% of these sightings. It appears that abnormal operating conditions must be largely responsible, because the observation frequency was too high to be attributed to routine operations like condensate flashing or liquid unloadings alone All other observations were due to anomalous venting from dehydrators, separators and flares.

The report that this report references in this paragraph is the Omara Marcellus 2016 report which did – as we described earlier – at least for conventional low production wells demonstrate that the primary emissions sources were storage tanks. Here, however, the authors cannot accept the reality that storage tanks, dehydrator vents, separators and flare are the likeliest sources of emissions and must postulate some “abnormal operating conditions” because to do otherwise would undermine their singleminded focus on expensive OGI LDAR requirements.

Another point the report makes and then ignores is:

Notably, the two largest sources of aggregate emissions in the EPA GHGI – pneumatic controllers and equipment leaks – were never observed from these aerial surveys.

This should be telling observation: *the two largest sources in the GHGI – pneumatic controllers and equipment leaks – were never observed in these aerial surveys.* But the report lets it drop while pursuing its skewed emissions estimates based on statistical manipulation of data.

These prior issues present an array of reasons why the Assessment of Studies report should have been extremely cautious about the methods it used to develop its inflated emissions estimates that the JEC has touted so frequently in its comments opposing the Reconsideration Rulemaking. The core of the Assessment of Studies emissions estimates hinges on how EDF takes the limited facility scale emissions information and kites it to national emissions.

Previously, the fundamental issue of taking short-term emissions observations and escalating them to daily and annual amounts was identified and challenged. But the more devious action taken in the report is the use of statistical tools to create emissions. Mark Twain once attributed

to Benjamin Disraeli this statement, “There are three kinds of lies: lies, damned lies, and statistics.” This report falls in the last category.

The following graph presents the emissions from the well sites used in the Assessment of Studies. It tracks the same type of emissions profile as the Super-Emitter report – large numbers of wells with little or no emissions and a few wells with some emissions. And, since these data are taken for the entire facility remotely, there is no information that defines the actual sources of the emissions. Similarly, since the data is collected from 2 seconds to 20 minutes, the representation of the emissions as daily emissions is speculative at best.

This chart also demonstrates the flaw in the arguments that emissions issues should be analyzed based on the percentage of emissions related to sales. For low production wells, the highest percentage emissions well is almost at the point where it is barely discernible. It emphasizes the lack of analysis of the underlying data. In this instance, using the EDF approach of calculating its percentages based on emissions divided by sales, the result would be 24.45 percent. Any good engineer would look at this result and question losing a quarter of its sales volume. The question then would be whether something unusual was happening that created this loss. But, clearly, an EDF analyst merely sees it a data point corroborating a preconceived notion of emissions.

It also accentuates the management of the data used for the Assessment of Studies report. The authors report some data was excluded from its analysis, stating:

And second, values reported as zero or below the detection limit (0.08 kg/h, 0.036 kg/h and 0.01 kg/h in Rella et al. (19), Robertson et al. (21), and Omara et al. (20), respectively) were treated as censored data points (see below). Such censoring

applied to 78 (40%) and 18 (35%) measurements in the Barnett and Fayetteville, respectively.

This statement implies that the authors concluded that low emissions data would reduce the emissions estimates and, therefore, it was inconsistent with the intended result of the study.

All of these pieces point to a consistent conclusion regarding the validity of the Assessment of Studies report. It builds on data that is not consistent and then excludes data it does not want. But, the final aspect of its effort is telling. The key to the development of the Assessment of Studies is its statistical manipulation of its data to develop emissions values where it does not have data. Here are some important statements by the authors:

We assume our underlying emissions pdfs are lognormal, which is expected in a system where many independent random and multiplicative events can contribute to the occurrence and magnitude of emissions

and

Results from both tests applied to all of the datasets used directly in this work indicate that one cannot reject the null hypothesis that the site-level sample data arise from a lognormal population distribution

These are extremely weak arguments – “we assume ... emissions pdfs are lognormal...”; “...one cannot reject the ... hypothesis that the site-level ... data arise from a lognormal population distribution.”

If they are not lognormal distributions, the entire framework for the Assessment of Studies report becomes suspect. Correspondingly, looking at the nature of the site emissions data – with all of the flaws associated with the assumptions in evaluating that data – there is little to suggest it is a lognormal distribution.

These inadequacies and those described in the EID analysis of the report undermine the validity of the basis for arguing that the Assessment of Studies provides a basis for the fugitive emissions LDAR programs in Subpart OOOOa, particularly in their application to low production wells.

8. *A technical assessment of the forgone methane emissions reductions as a result of EPA's proposed reconsideration of the 2016 NSPS fugitive emissions requirements for oil and gas production sites (Omara Appendix G)*

This technical assessment was prepared by EDF to create a perception that EPA is understating the implications of its reconsideration of the Subpart OOOOa fugitive emissions requirements. Clearly, the first issue here relates to the vastly different views of the effectiveness of the fugitive emissions programs. But others are significant. For example, the assessment relies primarily on that same array of data that is used in other reports. As stated previously, fundamental issues with these data include the remote sampling nature that cannot distinguish between permitted or regulated emissions and fugitive sources and using limited time samples to create daily or annual emissions estimates. The assessment actually recognizes the challenge of distinguishing emissions.

The first issue in the assessment relates to differences between EPA calculations of the number of well sites that will be constructed between 2015 and 2025 for purposes of determining emissions changes between the current and proposed requirements. The assessment concludes that fewer wells will be drilled in the 10-year period. However, both analyses rely on

assumptions that are not reflecting changes in the development of American resources. Historic wells were typically one or two wells and low production well sites producing conventional formations are more likely to continue to be. However, the larger unconventional well sites frequently include far more wells because horizontal drilling allows for the well bores to be started close to each other. Consequently, both assessments may overstate the number of well sites needed to meet future production activities.

The second issue involves the approach the assessment uses to develop emissions factors for the different well types. As it states, the assessment uses information taken from existing well sites remotely to develop its factors. This raises a number of issues.

- A. Almost all of the data taken at these sites is based on existing operations that pre-date the Subpart OOOO requirements. Consequently, much of the fugitive emissions arise from equipment that differ from the sites developed under those requirements (and those required under Subpart OOOOa) such as pneumatic controllers. This inevitably skews the perception of the presence of fugitive emissions.
- B. The assessment concludes that EPA's use of emissions factors from the 1995 AP42 materials underestimates emissions. However, this is a highly disputable assumption since the American Petroleum Institute developed substantial new material showing that the factors overstate emissions and the failure rate of repaired equipment is longer than EPA's assumptions.
- C. The assessment attempts to use information from 300 wells in the Barnett Shale to develop a reduction in total emissions to represent fugitive emissions. However, there is no basis to suggest that this approach is appropriate for all categories of wells. For example, a number of reports on low production wells suggest that the primary emissions sources at those sites are storage vessels. Storage vessel emissions are comprised of essential vents and open hatches that should be closed. A massive OGI fugitive emissions program is not necessary to address either emission.
- D. The assessment even states that "...fugitive emissions from storage vessels dominate site-level emissions..." But, it uses this statement to argue that EPA's emissions factor for storage tanks "...is likely a significant underestimate for these sources." However, for the new sources being considered in this assessment, storage vessels would be regulated under Subpart OOOO requiring either a vapor recovery/control system or management to keep the emissions below 4.0 tons/year. And, as described previously, storage vessels at existing low production facilities would likely be far lower than that.

Ultimately, this assessment has to be recognized for what it is – a collection of manufactured emissions estimates for the sole purpose of arguing that EPA is understating the implications of the Subpart OOOOa reconsideration when there is ample evidence that EPA has overstated both emissions and the effectiveness of its current program.

9. Response to methane synthesis critiques (Hamburg)

This document is a response rebutting analyses of the EDF report addressed previously. It essentially argues that those analysts are too stupid to understand the EDF report. The report responds to statements in an Energy In Depth assessment of the EDF report. The EDF analysis is provided here:

The Environmental Defense Fund (EDF) has released a myriad of studies on natural gas system methane emissions over the past six years that have found low leakage rates between 1.2 and 1.5 percent of production. Five such studies are featured in the following EID graphic.

Studies Confirm Low Methane Leakage Rates From Natural Gas Development

So the fact that a new EDF study released today finds methane leakage rates of 2.3 percent — well above what EDF-led research has previously found and “60 percent higher than the U.S. EPA inventory estimate,” according to the report — begs the question: What changed with regard to EDF’s methodology for this study that yielded a much higher leakage estimate than its past research has shown?

Turns out, quite a lot changed, and most of the changes raise red flags regarding the study’s conclusions. Not only did the authors of the new EDF study — which includes no new measurements and instead calculates national methane emissions based on past studies — opt not to use past EDF research as a basis for their emissions calculations, it relies exclusively on five far less comprehensive facility-level studies that lacked industry participation to arrive at its conclusion of higher U.S. emissions than previously reported. In contrast, an “alternative” calculation, based partially on EDF’s past studies, that finds emissions in line with current EPA estimates is buried in the study’s supplemental data and is not even mentioned in the report.

These are just two of several key issues regarding the manner in which EDF conducted this study that appear aimed at producing the most extreme emissions estimate possible ahead of the 27th annual World Gas Conference (WGC), which begins Monday in Washington, DC. Here is a deeper look at each issue.

#1. Exclusive Use of Facility-Scale Study Data Goes Against National Academy of Sciences' Recommendations and Likely Exaggerates Emissions

This study's national methane emissions estimate is based entirely on downwind, facility-based studies. From the report:

“In this work we integrate the results of recent facility-scale BU studies to estimate CH₄ emissions from the U.S. O/NG supply chain, and then we validate the results using the TD [top-down] studies.”

However, a recent National Academy of Sciences (NAS) report aimed at improving national methane emissions inventories recommends a more comprehensive approach combining “bottom-up” measurements — both of the component- and facility-level variety — along with “top-down” measurements:

“Coordinated, contemporaneous top-down and bottom-up measurement campaigns, conducted in a variety of source regions for anthropogenic methane emissions, **are crucial for identifying knowledge gaps and prioritizing emission inventory improvements**. Careful evaluation of such data for use in national methane inventories is necessary to ensure representativeness of annual average assessments.”

EDF has conducted studies combining the comprehensive top-down/bottom-up methods recommended by NAS before. Zavala-Araiza et al. is the most notable example, and that study found a methane leakage rate of just 1.5 percent. Just as notably, a recent National Energy Technology Laboratory study based on Zavala-Araiza et al. data estimates national methane emissions at 1.65 percent. That report involved several of the co-authors of this most recent EDF study that reached much different conclusions.

The new EDF report argues that using facility-level measurements exclusively is appropriate because component-based studies can “under-sample abnormal operating conditions” such as malfunctions and large leaks. But this rationale ignores flaws with facility-level measurements that can lead to overestimation of emissions. For instance, facility-level measurements can capture episodic emissions, such as liquids unloading, and inaccurately characterize them as normal emissions that would be occurring 24 hours a day, seven days a week. The latter issue can be exacerbated when researchers lack a fundamental understanding of the facilities where they are taking measurements, which brings us to the next major issue with the study.

#2. Lack of Industry Collaboration Goes Against National Academy of Sciences' Recommendations

With regard to the ground-based, facility-level studies used as the basis for estimating national emissions in this report, the report's supplementary information document notes:

“Sites were reported to be sampled on a quasi-random basis **without advance operator knowledge**.”

Not only does EDF admit that some of the studies used did not conduct truly random sampling, it admits that industry wasn't involved in these studies on any level. This again flies in the face of recommendations made in the NAS report, which states:

“[V]erifiability is the bedrock upon which inventories should be built if they are to be widely applicable to policy needs.”

The lack of industry participation is surprising, considering EDF's past methane research is well known to have been a collaborative effort between EDF, academia and industry, a fact EDF has frequently touted. But even more surprising is EDF's justification for excluding industry from participating in this particular study. From the report:

“Operator cooperation is required to obtain site access for emission measurements. Operators with lower-emitting sites are plausibly more likely to cooperate in such studies, and workers are likely to be more careful to avoid errors or fix problems when measurement teams are on site or about to arrive. The **potential bias** due to this ‘opt-in’ study design is very challenging to determine. We therefore rely primarily on site-level, downwind measurement methods with **limited or no operator forewarning** to construct our BU estimate.”

Not only does EDF fail to provide a single reference to back up this claim of “potential bias” that it claims necessitated it to use the methodology highlighted above, but none of the five co-authors of this report, who were also the lead authors of past EDF methane research that was conducted in close concert with industry, have ever publicly claimed any “bias” whatsoever. Not once.

EDF's assertion appears to be purely speculative in nature and also appears to be an excuse to use these studies as a basis for exaggerated national emission estimates.

#3. “Alternative” Emissions Estimate That Is In Line With EPA Greenhouse Gas Inventory (And Past EDF Research) Is Not Included In Report

In the supplemental materials document for this report, EDF includes the following “alternative” national emissions estimates based on source-based reports, several of which are past EDF studies.

Source: Table S3	GHGI	Source-based EDF estimate (Gg CH ₄ /yr) – Alternative EDF estimate	Site-based estimate (Gg CH ₄ /yr) – Primary Method
Total U.S. Oil and Gas Supply Chain	8,100 (6,800 – 10,000)	8,800 (8,400 - 9,700)	13,000 (12,000 - 15,000)

Source: Alvarez et al. supplementary materials

This “alternative” estimate finds the national methane leakage rate is 1.4 percent, which (not surprisingly) not only aligns with past EDF studies, but also the [EPA Greenhouse Gas Inventory](#).

Remarkably, the data from this “alternative” estimate isn’t mentioned at all in the actual report, even though EDF notes that an extensive list of source-based studies featured in the supplemental data of the report has “dramatically improved understanding of the sources and magnitude of CH₄ emissions from the industry’s operations.”

EDF also argues that its “primary” estimate — which, again, is based solely on facility-level studies — is in line with aggregate average emissions found in the following nine “top-down” studies based on emission measurements largely collected via aircraft measurements.

“When the BU estimate is developed in this manner, direct comparison of BU and TD estimates of CH₄ emissions in the nine basins for which TD measurements have been reported indicates agreement between methods...”

Table S2. Reported estimates of O/NG CH₄ emissions from aircraft-based top-down (TD) studies, listed in decreasing order of natural gas production. Italicized values were calculated in this work; shaded rows indicate a second independent, statistically consistent set of reported measurements in two basins (not used directly in this work in favor of the more recent results based on more intensive sampling). Uncertainties are 2-sigma values calculated from reported uncertainties.

#4. Attempts to Discredit Study That Finds Misrepresentation of Episodic Events Can Lead to Inflated Emissions Estimates Via Daytime Bias

Another factor that can lead to facility-scale measurements overestimating actual normal emissions is the fact that such methods are conducted in the daytime and, thus, can capture emissions from episodic events — such as liquids unloading — that are conducted during the day and inaccurately extrapolate them as if they are constant. This fact was further confirmed by a recent peer-reviewed NOAA study of the Fayetteville Shale [covered](#) by EID last year.

Perhaps anticipating that 2017 study would be used to call this new EDF report's conclusions into question, EDF attempts to discredit the NOAA study in the paper:

“[W]e consider unlikely an alternative hypothesis that systemically higher emissions during day-time sampling cause a high bias in TD methods.”

“[T]here is no reason to expect daytime bias in the kinds of abnormal operating conditions that are thought to characterize high-emitting production (and gathering) sites, which operate continuously. In fact, it is plausible that abnormal emissions could actually be higher at night because they are less likely to be found and corrected in the absence of operators.”

The above claim is directly contradicted by the following, which acknowledges the validity of the NOAA Fayetteville study, but claims it isn't relevant to other basins.

“O/NG emissions are systematically higher during daytime hours when TD and BU measurements have been made, and lower at night. This situation was reported for the Fayetteville Shale but appears to be unique because the effect is caused by manual liquids unloadings, which represent a much higher fraction of total production emissions than in any other basin.”

The fact is, events such as liquid unloadings *are* common in other basins and downwind measurements, such as the ones used as the basis for this EDF analysis, do tend to be higher because they are conducted during the day.

#5. Despite EDF's Alarmist Characterizations, Natural Gas' Climate Benefits Remain Clear

The report claims the oil and natural gas development emissions level estimated in this report combined with carbon emissions from current natural gas combustion is having the same climate impact as coal in the short term (20-year timespan):

“Indeed, our estimate of CH₄ emissions across the supply chain, per unit of gas consumed, results in roughly the same radiative forcing as does the CO₂ from combustion of natural gas over a 20-year time horizon (31% over 100 years). Moreover, **the climate impact of 13 Tg CH₄/y over a 20-year time horizon roughly equals that from the annual CO₂ emissions from all U.S. coal-fired power plants operating in 2016 (31% of the impact over a 100-year time horizon).**”

But as alarming as that claim might be, it is essential to note that natural gas maintains clear climate benefits over other traditional sources even at much higher leakage rates than purported by this study.

A recent hydraulic fracturing issues brief published by Washington D.C.-based environmental think tank Resources for the Future (RFF) notes:

“If more than about 4% of the natural gas produced in the United States is emitted as methane (rather than being burned), the climate benefits of gas’s displacement of coal disappears over a 20-year time frame. If the time frame is 100 years, the leakage rate would have to be more than 8% for natural gas to be a climate loser relative to coal.”

The following International Energy Agency (IEA) graphic illustrates RFF’s point, showing natural gas maintains its climate benefits even at high leakage rates and regardless of time-frame considered.

Greenhouse-gas emission intensity of natural gas compared with coal IEA analysis

GWP20 = global warming potential over a 20-year timeframe
GWP100 = global warming potential over a 100-year timeframe, based on the ranges from the Fifth IPCC Assessment Report (IPCC, 2014)

Conclusion

This EDF study spends an inordinate amount of time explaining *why* its conclusions are plausible rather than explaining *how* it reached its conclusions. And it’s clear why — once one digs into the report’s supplemental information, it’s clear that the conclusions are based on some pretty shaky assumptions and speculation that runs counter to established and/or recommended best practices for such research.

But at the end of the day, the EDF study is not only an outlier in terms of the overall body of current methane research — it’s also an outlier with regard to EDF’s collective methane research, which has consistently found leakage rates between 1.2 and 1.5 percent. In the meantime, EPA data show oil and gas methane emissions have declined 14 percent since 1990 even as oil and natural gas production have skyrocketed. Combined with the fact that increased natural gas use has helped contribute to the best air quality of the modern era and the

lowest carbon emissions in 25 years, it is clear that the shale revolution has been a win-win for the economy and environment.

As addressed in specific comments on the EDF report, despite EDF's characterization of the report as "...the culmination of an extensive amount of research...examining methane emissions from the U.S. oil and gas supply chain", the material is an aggregation of various reports that fail to change the reality that the data suffers from the limitations that it is dependent on remote sampling that cannot distinguish sources and that it estimates daily or annual emissions from short term data collection.

In addition to relying on the studies above, the JEC attempts to further justify its positions by identifying new information that it believes points to support. These three items are, in reality, as flawed as support documents as the studies the JEC relies on.

1. *Very Strong Atmospheric Methane Growth in the Four Years 2014 – 2017: Implications for the Paris Agreement*

The environmental activists argue that:

A new paper approved for publication by the American Geophysical Union indicates that there has been rapid growth in atmospheric methane since 2007, including "remarkable growth" in methane concentration between 2014 and 2017. One reason that the paper finds for this increase in atmospheric methane is from "very large" emissions of methane from the oil and natural gas sector. The paper concluded that "[r]educing methane emissions is feasible, *especially from fossil fuel sources*, and would have rapid impact on the global methane burden."

New research on rising global methane levels is much more complex than the environmental activists suggest in their comments. While, the report details that oil and natural gas is still a source of methane, it also explains that "fossil fuel emissions are falling as a proportion of the total methane emission." Further, the study notes,

"However, there is evidence (Schwietzke et al., 2016) that natural gas emissions per unit of production have declined significantly in recent years, and rapid improvements and investment in leak detection and reduction have likely cut the percentage of gas leaked from gas industry production facilities."

More importantly, and as media reported, biogenic sources of methane are thought to be a more likely cause of the increases. Lead author of the study, Professor Euan Nisbet of Royal Holloway, University of London, told the Guardian, "We have only just started analysing our data but have already found evidence that a great plume of methane now rises above the wetland swamps of Lake Bangweul in Zambia." Notably, Zambia is not a country with significant – if any – oil and gas production. The *Guardian*, which has vocally supported a "Keep It In the Ground" agenda with regard to fossil fuels in recent years, had a much different take on the study's findings than the activists:

"Studies suggest these increases are more likely to be mainly biological in origin. However, the exact cause remains unclear. Some researchers believe the spread of intense farming in Africa may be involved, in particular in tropical regions where conditions are becoming warmer and wetter because of climate change. Rising numbers of cattle – as well as wetter and warmer swamps – are producing more and more methane, it is argued."

The activists' typical approach of pulling statements out of context here is clear.

More recently, a report by National Oceanic and Atmospheric Administration (NOAA) and University of Colorado scientists entitled, "Long-Term Measurements Show Little Evidence for Large Increases in Total U.S. Methane Emissions Over the Past Decade", calls into question some of the fundamental approaches to assessing methane emissions that have led to excessive emissions estimates. That report summarizes the issues as follows:

In the past decade, natural gas production in the United States has increased by ~46%. Methane emissions associated with oil and natural gas productions have raised concerns since methane is a potent greenhouse gas with the second largest influence on global warming. Recent studies show conflicting results regarding whether methane emissions from oil and gas operations have been increased in the United States. Based on long-term and well-calibrated measurements, we find that (i) there is no large increase of total methane emissions in the United States in the past decade; (ii) there is a modest increase in oil and gas methane emissions, but this increase is much lower than some previous studies suggest; and (iii) the assumption of a time-constant relationship between methane and ethane emissions has resulted in major overestimation of an oil and gas emissions trend in some previous studies.

Moreover, to supplement the point that industrial actions are reducing methane emissions, as described previously, in the U.S. new information demonstrates that methane emissions intensity is declining.

2. Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2017

With regard to the Green House Gas Inventory, the activists state:

Furthermore, EPA's latest draft greenhouse gas inventory, released February 12, 2019, shows that methane emissions increased slightly for the oil and gas sector between 2016 and 2017. While EPA's inventory significantly underestimates methane emissions from the oil and gas sector, as discussed *supra* Section II, the latest draft inventory continues a pattern showing that overall methane emissions remain unacceptably high.

The activists carefully address emissions changes only from 2016 to 2017. Energy In Depth addressed the Inventory more fully in the following assessment:

U.S. greenhouse gas emissions fell significantly from 2005 to 2017, even while oil and natural gas production skyrocketed, according to the Environmental Protection Agency's draft 2019 greenhouse gas inventory (GHGI).

The draft GHGI data show total U.S. CO₂ decreased nearly 14 percent, while methane emissions were reduced by more than 4 percent since 2005. Meanwhile, U.S. oil and natural gas production increased more than 80 percent and 51 percent, respectively, according to the Energy Information Administration.

CO2	1990	2005	2013	2014	2015	2016	2017
Natural gas systems	30.0	22.6	25.1	25.5	25.1	25.5	26.3
Petroleum systems	8.9	11.6	25.2	29.7	31.7	22.2	23.3
<i>Combined</i>	38.9	34.2	50.3	55.2	56.8	47.7	49.6
Methane							
Natural gas systems	193.9	171.9	166.3	165.8	167.8	164.7	166.2
Petroleum systems	42.1	36.7	41.6	42.1	39.5	38.2	37.7
<i>Combined</i>	236.0	208.6	207.9	207.9	207.3	202.9	203.9
Total U.S. CO2	5,122.0	6,131.5	5,524.0	5,574.9	5,427.0	5,310.5	5,279.7
Total U.S. Methane	780.8	692.1	664.0	663.1	661.8	653.4	663.3

Source: Table ES-2, EPA draft “Inventory of U.S. Greenhouse Gas Emissions and Sinks,” February 2019; Data: million metric ton CO2 equivalent

The activists also dismiss the information that they report by referring to their recurring analyses that the Inventory underestimates emissions. However, as described above, the basis for alleging higher emissions is based on limited and flimsy analyses. Moreover, while the total methane emissions that are reported in the Inventory amount to about 3.86 percent of the total inventory, the contribution from the oil and natural gas production would be 1.2 percent.

3. Plugging the Leaks: Why Existing Financial Incentives Aren’t Enough to Reduce Methane

The activists pull from this report the following assessment:

Finally, a new policy brief from the University of Pennsylvania highlights the need for standards to reduce fugitive methane emissions from the oil and gas sector because the value of recovered product alone may be lower than the cost to control the emissions. In other words, often industry is not economically incentivized to control the emissions based on its own cost-benefit analysis. Capturing these emissions is important because of the social damage from climate change and health and safety harms from emissions, which operators do not factor into their own cost-benefit analysis. Because industry does not take these societal costs into account, the need for strong federal action is clear as “global damages reflect real economic risks to the United States, as climate change will impact the global economy.”

There are two fundamental issues here that arise on a recurring basis. The first relates to the assessment of cost-benefit analysis in the regulatory arena, particularly with regard to low production wells. Most cost-benefit analyses develop assessments based on valuing the cost of the regulatory requirement and the amount of the recovered emissions. It produces a value in dollars per unit of emissions, e.g., \$/ton or \$/mcf. What these cost-benefit analyses fail to address are the economic implications for a facility including their operating costs. The Independent Producers comments have submitted assessments regarding how the failure to look at the full implications of regulations can distort conclusions about their “benefits” when in fact they will cause operations to cease.

The second issue relates to the development of social benefits from regulations in the context of global implications. The issue of “social cost” calculations is a complicated one. Developing social cost values relies on a wide variety of assumptions that can be sound or speculative. If these values are not well founded and reliable, social cost calculations can be manipulated to produce whatever value is needed to generate a “cost effective” regulations. Essentially, the process becomes a “black box” that produces a supportive result.

In 2015, NERA Economic Consultants addressed the implications that differing assumptions can have on social cost benefit determinations as a part of comments on the original proposal of Subpart OOOOa regulations. It stated in part:

The U.S. Environmental Protection Agency (EPA) proposed emission standards for methane (CH₄) and volatile organic compounds from new and modified sources in the oil and natural gas sector (referred to as “the Proposed Rule” in this report) on August 18, 2015. Accompanying this Proposed Rule is a Regulatory Impact Analysis (RIA) that is required under Executive Orders 12866 and 13563 for all major rulemakings from Executive Branch agencies. The RIA contains estimates of the net benefits of each of several options that the Proposed Rule is considering, which are equal to each option’s estimated benefits minus its estimated compliance costs.

Our comments address technical issues with the RIA’s monetized benefits estimates, which are entirely based on potential reductions in future climate change due to CH₄ reductions, using a concept called the social cost of methane (SC-CH₄). We demonstrate that EPA’s estimates of the benefits are: 1) highly uncertain and very likely overstated; and 2) lack the appropriate peer review that is necessary for use in supporting regulatory policy. We also explore the implications of these issues with the Proposed Rule’s net benefits estimates, and find they are far more likely to be negative than positive.

More specifically:

- We conclude that the RIA’s estimates of benefits from CH₄ reductions using its SC-CH₄ estimates are highly uncertain and likely overstated for multiple reasons:
 - The EPA’s SC-CH₄ estimates are based upon a single study (Marten *et al.*, 2014) whose estimates are significantly greater than, and inconsistent with, available estimates in other published papers (see Section II for a summary of the rest of the literature).
 - EPA relies on SC-CH₄ estimates that reflect global benefits rather than domestic benefits, a practice that is contrary to the Office of Management and Budget’s (OMB’s) *Circular A-4* (OMB, 2003) and inconsistent with the theoretical underpinnings of benefit-cost analysis that endow the method with its ability to guide a society towards policies that will improve its citizens’ well-being. *Circular A-4* calls for use of domestic benefits, and notes that any estimates of non-domestic benefits should be presented separately. EPA’s use of global SC-CH₄ benefits estimates (and failure to

even present domestic benefits, which are readily obtained. The RIA includes a 2.5% discount rate in its range of benefits, which is inconsistent with the short atmospheric lifespan of CH₄. Its inclusion overstates the upper end of EPA's SC-CH₄ estimates, and hence its net benefits.

- Marten *et al.* (2014) have used assumptions regarding indirect effects on radiative forcing from changes in tropospheric ozone and stratospheric water vapor levels that lack clear support from the scientific literature. This assumption, which is uncertain and not validated, could be a substantial source of overstatement in EPA's SC-CH₄ estimates. For example, compared to a zero indirect effects assumption, it increases EPA's SC-CH₄ estimate by about 36% (when using a 3% discount rate).
- EPA's SC-CH₄ estimates are based on an average of five socioeconomic scenarios, four of which assume no incremental policies to reduce emissions in the future (also known as "business as usual" scenarios). Use of scenarios that assume no future emissions control policies to estimate the benefit of reducing a ton of emissions in the near-term overstates the SC-CH₄ estimates.
- The absence of a full scientific peer review of the methodology behind EPA's SC-CH₄ estimates calls into question the reliability of all of the RIA's estimated benefits and net benefits. We conclude more extensive peer review is especially warranted in this particular case for several reasons:
 - The integrated assessment models (IAMs) that were used to compute EPA's SC-CH₄ estimates were modified in a significant manner that has not been reviewed by the original model developers. Other researchers working in this field have not had a chance to concur or disagree with the methodological changes and alternative input assumptions that EPA believes cause its SC-CH₄ estimates to be so much greater than other published estimates.
 - The development of new SC-CH₄ estimates by modifying pre-existing IAMs to make "standardized" calculations is inconsistent with the concept of using multiple existing models to identify the range of uncertainty in the best-available science-based estimates.
 - EPA conducted an internal peer review process and the paper upon which it has relied (Marten *et al.* 2014) has been published in a peer-reviewed journal. However, those two types of reviews do not replace the need for a more rigorous independent scientific review in light of the types of changes described above. Additionally, EPA's internal reviewers lacked consensus on the use of the paper's SC-CH₄ estimates for evaluation of major regulations.

To provide a quantitative assessment of the sensitivity of the RIA's estimates of benefits and net benefits to the technical issues that we have identified, we have re-estimated the SC-CH₄ values under several alternative assumptions that we consider more reasonable. These alternative calculations include 1) eliminating from consideration the 2.5% discount rate, 2) limiting benefits to a domestic geographic scope, 3) using alternative assumptions regarding the indirect effects on radiative forcing, and 4) eliminating "business as usual" emissions projections as the reference point for computing future damages from a ton of incremental emission that would occur today. EPA's assumptions on these matters are discussed in Section III, along with our explanations for why our alternative assumptions are more reasonable for estimating SC-CH₄ for use in a Federal RIA. All of our alternative SC-CH₄ calculations have been made using the same IAMs that Marten *et al.* (2014) used to make their SC-CH₄ estimates.

Figure 1 provides a summary of how the EPA's SC-CH₄ estimates would change based on assumptions we consider either more reasonable or subject to too much uncertainty for EPA to rely on a single point estimate. The first row shows the range of SC-CH₄ included in the RIA based on mean values using 2.5%, 3.0%, and 5.0% discount rates.⁹ Each subsequent row includes a revised range based on different cases we constructed to address some of the technical issues we identified in EPA's SC-CH₄ estimates. Case A removes from consideration the 2.5% discount rate because it is not appropriate given that the shorter atmospheric lifespan of CH₄ implies that the resulting climate benefits are not intergenerational. Cases B, C, and D then use a range of discount rates from 3% to 5%, while layering on additional alternative assumptions. Case B shows the range of SC-CH₄ estimates when limited to a domestic geographic scope. Case C removes the assumption EPA made on a 40% enhancement of radiative forcing due to indirect atmospheric effects (in addition to the change for Case B). Case D incorporates the same changes as in Case C, but also ensures the baseline emissions projection provides consistency between future emissions control policies and the current emissions reduction effort that is implied if the SC-CH₄ is to be used to make near-term emissions reduction decisions.

As Figure 1 shows, using all the alternative assumptions produces SC-CH4 estimates that are as much as 90% and 94% lower than EPA's SC-CH4 estimates for 2020 and 2025, respectively.

Figure 1. Alternative Estimates of SC-CH4 Reflecting Key Methodological Uncertainties

Case	Description	SC-CH4, \$ per tonne of CH4 (2012\$)			
		[% Change Relative to RIA Range]			
		2020		2025	
		Min	Max	Min	Max
RIA	RIA Option 2 (2.5%, 3.0%, and 5% discount rates)	587	1,721	702	1,900
A	RIA Option 2 (3.0%, and 5% discount rates)	587	1,309	702	1,508
		0%	-24%	0%	-21%
B	Domestic (U.S.) specific SC-CH4 values <u>averaged across all socioeconomic scenarios</u> from PAGE and FUND models.	106	210	130	248
		-82%	-88%	-81%	-87%
C	Domestic (U.S.) specific SC-CH4 values <u>averaged across all socioeconomic scenarios</u> from PAGE and FUND model <u>without the</u> <u>indirect effects.</u>	69	141	84	158
		-88%	-92%	-88%	-92%
D	Domestic (U.S.) specific SC-CH4 values for the <u>5th Scenario</u> from PAGE and FUND model <u>without the indirect effects.</u>	58	99	69	115
		-90%	-94%	-90%	-94%

Note: The Min and Max values span different discount rates, EPA's Low and High total costs, and climate benefits. For Cases B, C, and D, we do not report U.S-specific SC-CH4 estimates from the DICE model because it is a global model and does not include regional details (see Section III.2 for discussion).

The percentage changes in the SC-CH4 estimates would directly translate to percentage changes in the overall estimated benefits since there is not any change associated with the assumed tons of CH4 reductions. Thus, we find that the Proposed Rule is likely to result in net costs, rather than net benefits....

These comments demonstrate the substantial challenge of decision making utilizing a social cost framework for climate related regulations. Analysts who assess policies like the allegations in the activist referenced report produce conclusions that cannot be validated since they rely on determinations that are as speculative as social cost calculations.

Joint Environmental Coalition Supplemental Filing – February 21, 2019 – Criticisms of Industry Comments

The JEC submitted a supplemental filing on February 21, 2019, that asserted a number of criticisms of industry comments, many of which attack statements or information submitted by the Independent Producers. A number of these allegations are addressed below.

1. Demand for EPA to make all new data submitted during comment period available to public and reopen comment period

The JEC demands in its Supplemental Filing that EPA make all new data submitted in the comment period available to the public and reopen the comment period to address this additional data. The purpose of this demand is clearly to delay EPA's action to address the proposed reconsideration of Subpart OOOOa. Ironically, when comments submitted by EDF on the "super-emitters" study during the comment period on the Subpart OOOOa resulted in the removal of the proposed low production well exclusion, the environmentalist were not crying foul. Not only should the concept of "what is good for the goose is good for the gander" apply, nothing prohibits EPA from relying on information submitted in response to an issue/topic raised in the proposed rule. The Independent Producers believe EPA needs to move forward on its proposed changes to Subpart OOOOa expeditiously.

2. Reduction in Monitoring Frequency at Well Sites remarks rely on flawed reports

The JEC criticizes comments addressing the validity of EPA's proposal to extend the monitoring frequency for both large wells and low production wells. Significantly, the basis for these criticisms is reliance on both the Assessment of Studies and Omara Appendix G reports. Both of these reports are essentially reassessments of the same information and reflect the same problems of remote, short-term data. Consequently, while they manipulate the data to create illusions of high emissions, these conclusions are no more valid than the estimates the JEC criticizes. Moreover, these data are based on facilities that largely preceded the requirements of Subpart OOOO and therefore do not reflect the technologies required by those regulations and their emissions reductions.

3. IPAA comments on super-emitter study – Zavala, Omara 2016, Appendix A

The JEC challenges the Independent Producers criticisms of the Super-Emitters report, offended by the characterization of the report as "specious". Specious can be defined as "having a false look of truth or genuineness". Recognizing that a key purpose of the JEC is the ultimate use of Subpart OOOOa to terminate the 770,000 low production wells in the United States using the nationwide existing source requirements of Section 111(d) through the application of costly OGI based fugitive emissions regulations casts all of the analytical efforts funded by or conducted by the JEC members into a clear light. Their efforts are targeted to this end result and their reports are tools to get there. In this context they must *appear* to be genuine, but their efforts are biased. They are at their core, specious.

The Independent Producers look to the key ingredients of the Super-Emitter report for corroboration. First, to prevent a discussion on the actual volumes of emissions, the report generates its percentage of production basis. Second, in creating this approach, it distorts the calculation by using a false basis to increase the percentage number. Third, it chooses to present only a portion of the data to elevate the appearance of higher percentage emissions. Fourth, it chooses to use a mathematical presentation that "flattens" data to make it look more a straight line. These are choices made to create a result to target low production operations.

The JEC argues that the Independent Producers criticize the Super-Emitter report for aggregating data from different studies. The criticism, if fact, is that these studies were not designed to evaluate low production wells, that those wells are merely components of a larger study, and that

the short-term collection of general data does not present a picture of low production wells to use as a basis for their regulation. The JEC obliquely acknowledges this reality in stating:

We agree that site-level measurements include intentional, vented emissions in addition to fugitive emissions.

However, it then argues that its solution is a costly LDAR program. Conversely, the Independent Producers believe that such a costly LDAR program would be a death blow for these small business facilities and that more analysis is needed before sentencing them to that fate.

The JEC also directs attention to the Omara Marcellus 2016 report touting another of its percentage of production emissions conclusions. However, as described above, a closer look at this report and its information on low production wells finds that storage tanks were the dominant emissions sources at the 60 percent these facilities but their emissions would fall well below the threshold for regulation under the current CTG. Equally important, an OGI LDAR program is not needed to find open thief hatches on tanks.

4. Reference to 1000 well study – Appendix G

The JEC further turns to its Assessment of Studies document for another attack on low production wells, emphasizing its 1000 wells analysis and its calculation of higher emissions values based on this report.

As described previously in evaluating the Assessment of Studies document, these conclusions are wholly flawed. First, while the Assessment of Studies document considers 1000 wells, not all of these are low production wells. Second, a substantial share of the 1000 wells are the same wells that were in the Super-Emitters report. Third, the Assessment of Studies document does nothing to quality control this old data to determine what it sampled or how accurately. Fourth, contrary to the JEC statement, these data do not distinguish between fugitive and permitted emissions and suffer from all of the limitations of taking short term data and extrapolating it to daily and annual values. Fifth, the Assessment of Studies appears to have eliminated all of the zero and low emissions sites from its analysis thereby skewing the emissions estimates high. Sixth, the entire report is an exercise in generating emissions values where data does not exist.

Using this faulty, conclusion driven Assessment of Studies report as a basis to judge the regulation of low production wells is wholly inappropriate.

5. Carbon Limits

The JEC alleges that the Independent Producers misinterpret the Carbon Limits report countering that the report shows that OGI LDAR programs are cost effective in the aggregate. The Independent Producers were not concerned about the aggregate conclusions; the focus was on low production wells. Here, there were several differences. First, as noted previously, like most other analyses and EPA's calculations, the value of recovered methane is too high – \$4.00/mcf versus \$1.67. Second, the JEC fails to mention that the Carbon Limits report found that fugitive emissions at well sites represented only 17 percent of their methane emissions. These emissions are presumably the target of an OGI LDAR program. Third, this reality likely leads to the Carbon Limits report's assessment that an infrared camera based LDAR program is not cost effective for 85 percent of well sites based on the \$4.00/mcf methane value and a larger percentage if a more realistic value (e.g., \$1.67/mcf) were used.

6. *Fort Worth comments*

The JEC criticizes the Independent Producers assertions that the use of the Fort Worth dataset to characterize low production wells. The JEC then goes on to state:

Environmental Commenters agree that it would be arbitrary and capricious for EPA to rely on this evidence as a sole basis for subcategorizing low production wells and developing a separate low-production well model facility. *See* Joint Environmental Comments at 94-100. However, uncertainties regarding the representativeness of the Fort Worth dataset for low-production wells indicates that EPA lacks sufficient data to regulate low-production wells as a separate category, *not* that EPA may exempt these wells from regulation, as IPAA argues. These concerns instead underscore that EPA lacks meaningful evidence to contravene its conclusion in the 2016 Rule that “a low production well model plant would have the same equipment and component counts as a non-low production well site.” 81 Fed. Reg. at 35,856. Indeed, the Fort Worth dataset shows that these low producing wells have high absolute emissions and component counts similar to those in EPA’s non-low production model facility. *See* Joint Environmental Comments at 97-99.

This analysis turns the entire concept of regulation on its head. Under its reasoning, the most appropriate basis for regulating would be when EPA knows nothing about the emissions from a potential regulated source. Returning to the 2016 Subpart OOOOa rule, EPA initially chose to exclude low production wells from regulation. It then relied on the specious Super-Emitter study to argue that regulation was necessary based not on emissions information but on purported equivalency of component counts. Now, when EPA attempts to recognize that distinctions exist between large and low production wells, the JEC argues that it should not and then tries to cover its argument by alleging that the component counts really are not that different.

The points that the Independent Producers raise relate to the challenge facing EPA in trying to characterize low production wells using the 25 Fort Worth wells. The Independent Producers do not believe that component counts are a valid basis for developing emissions analyses for low production wells. However, if EPA chooses to go that route, it must have a more substantive basis than 25 wells in one basin. This is particularly significant with regard to the implications of Section 111(d) that would affect 770,000 wells nationwide. In the Independent Producers comments, the flaws in the use of the Fort Worth wells are laid out relating to questions about their representativeness, whether they are in fact low production wells and the validity of the emissions factors that drove the emissions estimates. These flaws generate the need for EPA to develop a more thorough and accurate understanding of low production wells.

In that context, the JEC argument that low production well regulation should go forth and expand perhaps 400 times the annual rate of affected facilities that EPA projects in Subpart OOOOa demonstrates its true intent to cripple and destroy America’s low production wells.

7. *IPAA low production well statements*

The JEC further challenges the Independent Producers submission of information on component counts for low production wells across a broad spectrum of states. As the JEC states:

IPAA itself admits this data is “not intended to be presented as statistically accurate or fully representative of the population of low production wells.”

The purpose of submitting this information must be considered in the context that it was intended. As the Independent Producers have stated in submitted comments:

The EPA should defer any fugitive emissions regulations of low production wells until it obtains information on emissions from low production wells. Specifically, the EPA should first determine whether a low production well program is appropriate and cost-effective, and then design a program based on accurate emissions information from low production wells. The Department of Energy ("DOE") is initiating a research effort to provide specific low production well emissions information that can inform these decisions and actions.

The information submitted in the Independent Producers comments on component counts at low production wells across the nation was generated to emphasize to EPA that creating a model facility for the purpose of making a regulatory assessment required a far broader framework than the 25 Fort Worth wells. Necessarily, the information had to be voluntarily provided by small business operators in the limited time frame of the public comment period. The Independent Producers do not and would not expect EPA to assume it has the kind of quality assurance that EPA would apply to data for regulatory development. However, it does demonstrate that there are substantial differences in the component counts of low production wells – and substantially different counts than the 25 Fort Worth wells. The burden is on EPA to support its regulations of low production wells. The previous Administration relied on information supplied on limited data that has since been proven not representative, if not misleading or unreliable.

8. Low production well – initial versus ongoing production

The JEC challenges the concept of classifying low production wells on the basis of current production rather than initial production. The JEC argues:

Such a classification would create an unworkable standard for both EPA and operators, as monitoring frequencies for individual wells would continually be in flux.

In fact, this type of classification decision on low production wells is made annually by hundreds of thousands of wells as a part of their determination as marginal wells for federal income tax purposes. The Independent Producers recommend in their initial comments an approach to address the definition of a low production well using the federal income tax code as a basis that would be far fairer and more workable than the approach in the proposed Subpart OOOOa reconsideration.

Joint Environmental Coalition Comments

The JEC also filed initial comments dated December 17, 2018. These comments raise a number of issues that distort the nature of methane emissions, the effectiveness of regulations and industry positions.

1. Methane Emissions Understated (Page 9)

The JEC submits its information on methane emissions but it does so without any context. For example, it reports the GHGI inventory values for natural gas and petroleum systems. Yet, without understanding these values in context they are meaningless. The JEC wants to suggest that a regulatory system would eliminate these emissions but that cannot happen.

First, these emissions estimates are developed for the full value chain – production through distribution to end users. Subpart OOOOa does not regulate all of these elements.

Second, these emissions need to be considered in the context of the entire GHGI. The Independent Producers address the exploration and production components of the GHGI. These amount to about 1.2 percent of the total GHGI.

Third, even if the revised hypothetical emissions values created by the JEC, were remotely accurate, the exploration and production components would still be less than 2.5 percent of the GHGI. However, the revised hypothetical emission values come from the Assessment of Studies document that these Keep It In the Ground organizations created. As described previously, the data supporting that analysis is fundamentally unsound for use in such a report, has not been quality controlled for accuracy, based on extrapolating short term data to annual emissions, and mathematically manipulated to generate emissions estimates to meet their Keep It In the Ground objectives.

2. Cost of Regulations (Pages 11-12)

The JEC regurgitates the ICF Study and the Waste Not study to allege that all methane regulations are cost effective. As shown above, while the aggregation of all regulations in the ICF study might be cost effective, individually, they are not. In particular, the OGI LDAR program described in the ICF Study raises significant cost effectiveness issues when realistic natural gas values are used and when the percentage of fugitive emissions at well sites are considered instead of all emissions that included permitted vents. These issues are more striking when they are viewed in the context of low production wells.

Similarly, the cost information in the Waste Not study is developed for a variety of requirements, most of which are separately addressed in Subpart OOOOa and are not a part of this reconsideration.

3. New scientific evidence (Pages 85-88)

The JEC castigates EPA for failing to use new information in its regulatory analysis. However, this new information is really analyses of existing information in a different format. At the heart of JEC Assessment of Studies that is referenced are data that suffer from a lack of onsite information, is taken for a short period of time, and is escalated to daily or annual emissions rate. These issues are repeatedly raised here because they pervade all of the JEC efforts to discredit the emissions factors used in the GHGI and to bolster the JEC arguments that far larger emissions are released.

A telling statement in the JEC submission demonstrates the nature of this report. It states:

Notably, the Synthesis found that methane emissions from the production and gathering segments of the oil and natural gas supply chain were particularly underestimated in EPA's inventory. Furthermore, the Synthesis postulates that this underestimate is due to high-emission events at a subset of sites—precisely the abnormal operating conditions identified and remedied by frequent fugitive emissions monitoring.

The report “postulates” that its estimates are accurate. And, of course, its solution is the implementation of a costly OGI LDAR program. The Independent Producers could postulate that the higher emissions incidents are related to a short-term maintenance activity or a tank

being filled, neither of which would be affected by an LDAR program. Since the Assessment of Studies chose not to work with producers during its data collection process, these issues cannot be confirmed.

4. *Low Production Wells (Pages 94-104)*

It is important to reiterate here what drives the JEC targeting of low production wells. These activists are committed to terminating production of American oil and natural gas. Their interest in low production wells reflects their commitment. They are not concerned with the new and modified sources of production that would be covered by Subpart OOOOa. These low production wells are largely small conventional wells drilled in reservoirs that have been producing for decades and have the potential to do so with low production wells. The JEC really wants to eliminate existing wells – the one million wells that would be captured through the implementation of Section 111(d) – particularly the 770,000 low production wells that cannot sustain the costs of the expensive OGI LDAR requirements of Subpart OOOOa.

The JEC present a number of claims regarding low production well decisions by EPA that demonstrate both creativity and duplicity.

The beginning part of this component of the JEC comments challenges EPA action to alter regulation of low production wells by referencing part of EPA's statement in 2016 removing its initial proposal to fully exclude low production wells. The full statement by EPA is included below with the JEC reference shown in italics:

Based on the data from DrillingInfo, 30 percent of natural gas wells are low production wells, and 43 percent of all oil wells are low production wells. The EPA believes that *low production well sites have the same type of equipment (e.g., separators, storage vessels) and components (e.g., valves, flanges) as production well sites with production greater than 15 boe per day. Because we did not receive additional data on equipment or component counts for low production wells, we believe that a low production well model plant would have the same equipment and component counts as a non-low production well site.* This would indicate that the emissions from low production well sites could be similar to that of non-low production well sites. We also believe that this type of well may be developed for leasing purposes but is typically unmanned and not visited as often as other well sites that would allow fugitive emissions to go undetected. We did not receive data showing that low production well sites have lower GHG (principally as methane) or VOC emissions other than non-low production well sites. In fact, the data that were provided indicated that the potential emissions from these well sites could be as significant as the emissions from non-low production well sites because the type of equipment and the well pressures are more than likely the same. In discussions with us, stakeholders indicated that well site fugitive emissions are not correlated with levels of production, but rather based on the number of pieces of equipment and components. Therefore, we believe that the fugitive emissions from low production and non-low production well sites are comparable.

Based on these considerations and, in particular, the large number of low production wells and the similarities between well sites with production greater than 15 boe per day and low production well sites in terms of the components that

could leak and the associated emissions, we are not exempting low production well sites from the fugitive emissions monitoring program.

What the selected quotation does not describe is that the referenced “stakeholders” were members of the JEC demanding that the Obama Administration regulate low production wells despite the absence of sound emissions data. These efforts were wrapped around the specious Super-Emitters study to give EPA some thread of a basis to cover low production wells. Now that EPA recognizes that low production wells are different, the JEC vents its outrage that the basis is inadequate.

The Independent Producers also recognize that EPA’s effort to create a model low production well, while appropriate and appreciated, is a flawed effort but for different reasons. The Independent Producers believe that low production wells will emit less because of lower production, but in the current proposal the basis relies on component counts and that approach must be addressed. As stated previously, there is no simple way to create a model low production well facility and relying solely or primarily on the Fort Worth wells is not an adequate basis to base regulations. EPA recognizes that the Fort Worth wells do show differences but those differences are actually much larger than the Fort Worth wells suggest. The Fort Worth data includes too many facilities that are not likely low production wells and this creates a component count that is too high.

The Independent Producers have presented information addressing these issues in initial comments and elsewhere in this submission. Consequently, this portion of these comments will focus on the JEC statements in their comments.

The JEC jabbars about component count differences between the low and high production Fort Worth wells but misses the key points. As presented previously, the Independent Producers also question the EPA component count analysis from the Fort Worth low production wells because the wells appear to be far larger than most true low production wells. But, the critical aspect of EPA’s analysis involves the components that drive the emissions estimates. Only two are significant.

The first is storage tanks. No one disputes that storage tanks can be sources of emissions. Tanks have vents to protect their integrity/safety. Tanks can also release emissions from open hatches or poor seals. The vent emissions are allowed; the hatch and seal emissions do not need an expensive OGI LDAR program to manage. Moreover, as shown in the Omara Marcellus 2016 data, these tank emissions are below the thresholds of regulation in the CTG.

The second key source is valve emissions. Here the emission factor used by EPA is questionable. The API reports on fugitive emissions programs established that the valve emissions factor was about 25 percent of the emissions factor used by EPA. Additionally, emissions from valves likely occur when the valve moves. For low production wells, valve movement is limited or nonexistent because the valves were designed for higher flows and as the well production declined, they essentially move to their maximum throughput position and stay there.

The JEC then complains that EPA’s new assessment of information on low production wells is inadequate and concludes that it should not make a proposed change because its recent studies purport to show the low production well emissions are higher than EPA believes.

The JEC complaint raises a broader question. If the information currently available to EPA to define emissions from low production wells is inadequate, then the information EPA used to regulate low production well was also inadequate. Consequently, EPA's initial decision to regulate creates potentially severe economic and energy production results without a valid environmental justification – results that could become catastrophic for existing low production wells if regulated under Section 111(d).

The JEC attempts to paper over these realities by dragging out its array of reports. As described previously, these reports were not low production focused efforts, rely on data that is inadequate to make regulatory decisions and – when studied – show that they provide little useful information on the fugitive emissions from low production wells. If anything comes from them, it would be that tank emissions are sources – equipment that does not need an expensive OGI LDAR program to address if they even emit at a regulated amount.

5. Fugitive Emissions Cost Analysis (pages 104-108)

The JEC introduces a new fugitive emissions cost analysis to support its position that a semi-annual OGI LDAR program is sustainable for low production wells. There are numerous issues with the basis for this analysis. At the outset the analysis is based on the emissions estimations from the JEC that are speculative at best. Secondly, the analysis creates its own LDAR cost estimate. Interestingly, these costs appear to be about twice the annual costs of the ICF Study. Third, the analysis addresses only new wells that were subsequently shut-in. Fourth, the analysis is based on gross revenues rather than net revenue. In the material supporting the analysis, M.J. Bradley states:

Newly drilled and modified wells get shut in when revenue falls below about \$150,000/year, regardless of what level of production is required to achieve this revenue target.

What is most compelling about this analysis is its inconsistency with other approaches.

For example, as described previously, the average price of natural gas has been \$2.22/mcf. Using this gross revenue number, the daily production number for a natural gas well to reach \$150,000 annually would be 185 mcf/d. This would be about twice the threshold for a low production well of 90 mcf/d and almost 8 times the average low production well nationally and 31 times the average Pennsylvania low production well. If the M.J. Bradley analysis was correct, no small well in Pennsylvania would be in operation.

Significantly, as the Independent Producers have discussed previously, gross revenues are not an appropriate approach to assess the validity of the cost effectiveness of regulations.

6. EPA Estimate of Domestic Costs Fatally Flawed (Pages 126-130)

The JEC challenges the EPA approach to its benefits analysis by criticizing its shift away from the social cost calculations EPA used in justifying its 2016 Subpart OOOOa regulations. This argument is bolstered in the JEC Supplemental Comments. However, as previously presented, analyses by organizations like NERA Economic Consultants have shown that social cost of methane determinations are highly questionable and can be manipulated to produce specific outcomes. For example, NERA concluded that a different look at the 2016 social cost of methane calculation would conclude that the regulation imposed net costs rather than benefits.

Response to AMEL State Equivalency Issues

1. EPA's State Equivalency Determinations are Lawful and Meet the Requirements of Clean Air Act 111(h)

In both the initial and supplemental comments submitted to the EPA by the JEC on December 17, 2018 and February 21, 2019 respectively, the JEC challenges the lawfulness of the state LDAR program equivalency determinations that EPA proposed in the Subpart OOOOa Reconsideration Rulemaking.² The Independent Producers disagree with these challenges and have outlined below support for the equivalency determinations and inclusion of the specific state LDAR programs as an alternative to compliance with the Subpart OOOOa LDAR program.

In the Reconsideration Rulemaking, EPA stated that “the 2016 NSPS Quad Oa allowed owners and operators to use the AMEL process to allow use of existing state or local programs” but EPA quickly realized the impracticality of this approach and further stated “it is possible that EPA would have over 300 identical applications from various owners and operators wanting to use the same state program at their affected facilities.”³ As the JEC points out in the summary table⁴ of the 111(h)(3) approvals issued by EPA in their initial comments, dated December 17, 2018, these AMEL approvals were for an alternative work practice at a single large facility, such as an ethylene plant, a stark difference to the lengthy and onerous process that would be involved in approving individual AMELs for use at hundreds of upstream oil and gas well and tank battery facilities. As common sense would dictate, EPA sought “to streamline the process, ensure compliance, and reduce regulatory burdens, and continued its evaluation of state fugitive emission programs after promulgating the 2016 NSPS OOOOa”.⁵

There are examples of EPA adopting state or local control requirements as alternative standards in other NSPS rules. For example, EPA incorporated, as an alternative standard into the Subpart Ja NSPS for petroleum refineries, the local requirements for flare minimization that were adopted by the Bay Area Air Quality Management District and the South Coast Air Quality Management District. In both of these cases, the Subpart Ja regulations establish the local flare minimization requirements “as an alternative to complying with the requirements” applicable to flares under Subpart Ja.⁶ Following this general approach, EPA was reasonable in identifying the current state and local standards that achieve emission reductions that are equivalent to, or greater than, the reduction obligations imposed by EPA under the Subpart OOOOa regulations, and incorporate those equivalent standards as alternative standards to meeting federal performance standards.

⁵ Reconsideration Rulemaking, 83 Fed. Reg. at 52080 (October 15, 2018)

⁶ 40 C.F.R. § 60.103a(g). Specifically, section 60.103a(g) provides: An affected flare subject to this subpart located in the Bay Area Air Quality Management District (BAAQMD) may elect to comply with both BAAQMD Regulation 12, Rule 11 and BAAQMD Regulation 12, Rule 12 as an alternative to complying with the requirements of paragraphs (a) through (e) of this section. An affected flare subject to this subpart located in the South Coast Air Quality Management District (SCAQMD) may elect to comply with SCAQMD Rule 1118 as an alternative to complying with the requirements of paragraphs (a) through (e) of this section. The owner or operator of an affected flare must notify the Administrator that the flare is in compliance with BAAQMD Regulation 12, Rule 11 and BAAQMD Regulation 12, Rule 12 or SCAQMD Rule 1118. The owner or operator of an affected flare shall also submit the existing flare management plan to [EPA].” *Id.*

A. The fugitive emissions equivalency determinations do not have to be quantitative; rather, qualitative factors can be included in determining equivalency

In the Reconsideration Rulemaking, EPA conducted its evaluation by “compar[ing] the fugitive emission components covered by the state programs, monitoring instruments, leak or fugitive emissions definitions, monitoring frequencies, repair requirements and recordkeeping to the fugitive emission requirements proposed in this action.”⁷

JEC’s first attacked this evaluation process by stating that “EPA must conduct a quantitative analysis to approve an AMEL and may not average qualitative factors”, and further stated, “equivalency determinations must be quantitative.”⁸ Clean Air Act 111(h)(3) does require that the AMEL will “achieve a reduction in emissions of any air pollutant at least equivalent to” the reduction under the NSPS.⁹ However, the term “equivalent” is not defined in statute, nor is there a formula for calculating equivalence, especially for fugitive emissions at issue here where the leaks are not required to be quantified and the federal requirement is not to reduce a certain volume of fugitive emissions but rather, to simply find and fix the leaks.

Equivalence is however explained at length in the 2008 rulemaking where EPA deemed OGI technology equivalent to Method 21 for leak detection (“OGI AWP”). In the OGI AWP, EPA states, “The emission control effectiveness of any work practice is a function of both 1) its ability to detect leakage and 2) the frequency of monitoring. An equivalent work practice may require more frequent monitoring, depending on its mass rate threshold for detecting leaks.”¹⁰

EPA further stated, “A more frequent monitoring requirement becomes necessary because higher mass emission reductions from large leaks, found earlier, are offset by some degree by smaller leaks which go undetected.”¹¹ Based on this standard in the statute, larger leaks found earlier and more frequently should reasonably be able to offset smaller leaks that may not be found as timely.

This 2008 equivalency analysis clearly assessed qualitative factors (i.e. frequency) and determined that if a technology is less sensitive at detecting leaks then it could be deployed more frequently and this can be analogous to a different technology that may be more sensitive but is deployed less frequently.

In the Reconsideration Rulemaking, not only does EPA compare various qualitative factors in proposing to approve these state programs, EPA’s evaluation process in the Reconsideration Rulemaking is almost identical to the evaluation EPA conducted previously in the OGI AWP as follows: “EPA believes that more frequent monitoring warrants allowance of a higher fugitive definition because larger fugitive emission will be found faster and repaired sooner, this reducing the overall length of the emission event.”¹²

Therefore, qualitative factors should be assessed because the state programs are not identical to the federal programs but that does not mean they are less stringent in their ability to find and reduce fugitive emissions. There are many different combinations of monitoring instruments,

¹⁰ Alternative Work Practice to Detect Leaks from Equipment Proposed Rule, 71 Fed. Reg. at 17404 (October 18, 2008)

¹¹ *Id.*

¹² Reconsideration Rulemaking, 83 Fed. Reg. at 52081 (October 15, 2018)

leak or fugitive emissions definitions, monitoring frequencies, repair requirements, etc... and these factors were all taken into consideration in crafting the state programs, many of which were included in a SIP for the air permit or program in which they have been incorporated, and SIPs must be approved by EPA. And again, fugitive emissions are not required to be quantified in Subpart OOOOa. Therefore, contrary to the JEC argument, these various program components *should be* compared “side by side” to determine the stringency or equivalence of the state program; this is the only feasible approach and is precedent based on the 2008 OGI AWP rulemaking.¹³

Last, in EDF’s recent paper entitled *Pathways for Alternative Compliance, A Framework for Advance Innovation, Environmental Protection, and Prosperity*, referring to the approval process of emerging technologies as an AMEL to Subpart OOOOa’s OGI requirement, EDF clearly states that non-quantifiable factors (i.e. frequency) must be taken into consideration to determine emissions reduction and therefore equivalency, as follows: “technologies with higher detection limits may yield greater or equivalent emission reductions than low detection limit technologies if used in a fashion that leads to quicker detection and mitigation of high emitting sources.”¹⁴ This is concurrent with EPA’s point in the Reconsideration Rulemaking and directly contrary to the Environmental Commenter’s statements on page 48 of their comments challenging EPA’s inclusion of frequency as a factor to weigh in the equivalency determination.¹⁵

B. Taken as a whole, some state programs are more stringent than federal programs (e.g. Texas)

The JEC claims that “even for the sources that are subject to state programs, those programs vary in stringency and may not secure the same level of reductions as EPA standards.”¹⁶ Then the JEC does some type of analysis for four states and compare the percentage of emissions reduced under the state program to the emissions reduced under the federal program. For Texas specifically, this graph doesn’t make sense and the footnote attempting to explain this data manipulation is nonsensical and confusing.¹⁷

Texas’ LDAR program in the oil and gas Standard Permit is more stringent across the board, for each variable examined, as opposed to the Subpart OOOOa program. This Texas LDAR program requires the use of Method 21, with a leak detection of 500 ppm, as opposed to OGI allowed under Subpart OOOOa, the monitoring frequency is quarterly, and repairs must be made within 15 days.¹⁸ And as the JEC point out, the frequency can eventually be reduced if less than 2% of leaks are found; therefore, it is impossible to calculate the emissions reductions this program will achieve in the future since that change in the frequency variable is unknown.

The state LDAR program AMEL option in Subpart OOOOa is relevant and useful where an operator is performing two concurrent LDAR programs at a site, and chooses to perform only the state program at the site in lieu of the federal program. This would only be done for the sites that

¹⁶ *Id.* at 50

¹⁷ *Id.* at 51

¹⁸ 30 TAC 116.620

are required to conduct both a state LDAR program required for the TX Standard Permit for example, and the Subpart OOOOa LDAR program. In Texas this would be for sites that have either a Standard Permit or Non-Rule Standard Permit. If the Texas program only covers a small percentage of sites (according to the JEC, it is only 5.5% of sites, and 12% of emissions)¹⁹ then so be it. The point is that for those specific sites, the operator would not have a duplicative LDAR burden, with overlapping timeframes and two different onerous administrative requirements that would result in no added environmental benefit.

C. State LDAR programs are included in state enforceable regulations and if promulgated through a State Implementation Plan (SIP), EPA retains oversight and enforcement authority over them

The JEC also attacks the lawfulness of the inclusion of these certain state programs by stating that the programs were not deemed equivalent through the requisite notice and comment process of 111(h)(3).

State LDAR programs have already been subject to the notice and comment process for the state regulation and/or air permitting program they are included in. These LDAR programs may also be included in a SIP and therefore, were subject to comment during the SIP promulgation process (*the Texas LDAR program, for example, is included in the Standard Permit and Non-Rule Standard Permit and is included in the Texas SIP*). These are valid state regulatory programs and should be recognize as such. This approach is similar to EPA's handling of storage tanks in Subpart OOOO where EPA allowed tanks, if shown to be below 6 tpy in a state or local enforceable permit, to be exempted from Subpart OOOO's storage tank provisions.²⁰ Similar to tanks that are permitted below federal threshold limits, these state LDAR programs are enforceable by the requisite state agencies and should recognized as adequate, alternative programs under the premise of cooperative federalism.

Further, if these state LDAR programs were promulgated under a SIP, EPA has, and will continue to have, oversight and enforcement authority over these programs.

D. Cooperative federalism should be recognized

Under the well-established premise of cooperative federalism, EPA should recognize these programs in full, including the states' recordkeeping and reporting requirements. The states have recordkeeping and reporting to ensure compliance with their programs and EPA should give proper deference to states for compliance assurance for their state program. If the state program is not adequate in EPA's opinion, then EPA needs to address this issue with the states.

Complying with two different recordkeeping and reporting schemes on the same site(s) is an enormous administrative burden with no added environmental benefit. And requiring the federal reporting (which would require some Subpart OOOOa recordkeeping requirements to be met in order to comply with the federal reporting), and monitoring plan defeats the purpose and any benefit from EPA approving these state programs in the first place.

Cooperative federalism is a central tenet of the Clean Air Act. Over the course of its fifty year history, the Act has evolved first from a set of general principles intended to guide States as they undertook regulation of air pollution sources, to an extensive number of more targeted standards

¹⁹ JEC comments to Reconsideration Rulemaking, December 17, 2018, page 51

²⁰ 40 CFR 60.5365

often prescribed by the federal government in the first instance and then implemented by the states. The principle that the States and the federal government will work in tandem to protect the nation's air resources is embodied throughout the Act. Congress, in section 101(a)(3) of the Act, declared air pollution control to be "the primary responsibility of States and local governments," 42 U.S.C. § 7401(a)(3), with the federal government providing "financial assistance and leadership," *id.* § 7401(a)(4).

For example, pursuant to section 110 of the CAA, while EPA develops the national ambient air quality standards, *see* 42 U.S.C. §§ 7408, 7409, states develop plans, called state implementation plans, to meet those standards. In that context, the U.S. Supreme Court has made clear that "[t]he Act gives the Agency no authority to question the wisdom of a State's choices of emission limitations if they are part of a plan which satisfies the standards." *Train v. Natural Res. Def. Council, Inc.*, 421 U.S. 60, 79 (1975). Similarly, under the CAA's visibility provisions, states have broad leeway to develop plans to combat regional haze that EPA cannot second-guess if the states have considered the statutory factors. *Am. Corn Growers Ass'n v. EPA*, 291 F.3d 1, 8 (D.C. Cir. 2002).

Section 111, the provision at issue here, fits squarely within the cooperative federalism tradition, with section 111(c) expressly calling on states to develop "a procedure for implementing and enforcing standards of performance for new sources" and calling on the Administrator to delegate "any authority he has ... to implement and enforce such standards." 42 U.S.C. § 7411(c)(1). The Supreme Court has affirmed that these cooperative principles are the heart of the CAA again and again. *See, e.g., Whitman v. Am. Trucking Ass'ns*, 531 U.S. 457, 470 (2001) ("It is to the States that the CAA assigns initial and primary responsibility for deciding what emissions reductions will be required from which sources."); *Union Elec. Co. v. EPA*, 427 U.S. 246, 269 (1976) ("Congress plainly left with the States, so long as the [NAAQS] were met, the power to determine which sources would be burdened by regulation and to what extent.").

State LDAR programs are precisely the sort of regulation over which states have special expertise, and they are proper subjects of state control.

Conclusion

The Independent Producers believe that these supplemental comments can better inform EPA as it makes the critical decisions related to the Reconsideration Rulemaking and would appreciate EPA's consideration of them.

The pending reconsideration gives EPA the opportunity to address regulatory actions that were rushed to a conclusion in 2016 without a full understanding of their consequences. Set forth herein, the Independent Producers reiterate and expand on key aspects of these actions – the treatment of low production wells, the importance of an LDAR program that can embrace new, cost effective technologies as they arise and the necessity of a coordinated federal and state regulatory structure to prevent unnecessary burdens on the regulated industry.

More explicitly, methane emissions from the natural gas and oil production sectors of the industry amount to about 1.2 percent of the GHGI and, as EPA is well aware, the Subpart OOOO regulations in place for facilities constructed after August 2011 are managing the major emissions from these operations. At issue here is the impact of some of the Subpart OOOOa regulations. These comments expand the Independent Producers concerns regarding the fugitive emissions requirements.

Specifically, the current Reconsideration Rulemaking proposal does not have a cost effective approach to the regulation of fugitive emissions from low production wells. Significantly, this issue is dramatically expanded because Subpart OOOOa is a methane based regulation that would result in the expansion of its scope from new sources to existing sources. As a result, instead of addressing 25,000 to 45,000 facilities per year, it would affect one million wells, 770,000 of which are low production wells. The regulations are not based on an adequate understanding of low production well emissions. They should not be applied as written. The Department of Energy (DOE) has initiated a study of low production well emissions that should be finished before low production well regulations are required and used to develop a sound low production well regulatory framework if one is necessary.

Similarly, the provisions regarding AMEL for emerging technology and state equivalency should be addressed to improve the ability of the regulated community to use better emerging technologies and to coordinate between federal and state requirements to avoid overregulation.

The Independent Producers appreciate the opportunity to submit these additional comments. If there are questions, please contact Lee Fuller (lfuller@ipaa.org or 202-857-4731) or James Elliott (jelliott@spilmanlaw.com or 202-361-8215).

Sincerely,

A handwritten signature in dark ink, appearing to read "Lee O. Fuller", with a large, stylized initial "L" and "F".

December 17, 2018

The Honorable Andrew Wheeler, Acting Administrator
US Environmental Protection Agency
1200 Pennsylvania Avenue, N.W.
Washington, DC 20460

VIA E-MAIL AND E-FILING

Re: Environmental Protection Agency's Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources Reconsideration at 83 Federal Register 52,056 (October 15, 2018)

Docket ID No. EPA-HQ-OAR-2017-0483

Dear Acting Administrator Wheeler:

The following Comments are submitted on the above-referenced proposed Reconsideration Rulemaking ("Reconsideration Rulemaking") on behalf of the following national and state trade associations: the Independent Petroleum Association of America ("IPAA"), American Exploration & Production Council ("AXPC"), Domestic Energy Producers Alliance ("DEPA"), Eastern Kansas Oil & Gas Association ("EKOGA"), Illinois Oil & Gas Association ("IOGA"), Independent Oil and Gas Association of West Virginia, Inc. ("IOGA-WV"), Indiana Oil and Gas Association ("INOGA"), International Association of Drilling Contractors ("IADC"), Kansas Independent Oil & Gas Association ("KIOGA"), Kentucky Oil & Gas Association ("KOGA"), Michigan Oil and Gas Association ("MOGA"), National Stripper Well Association ("NSWA"), North Dakota Petroleum Council ("NDPC"), Ohio Oil and Gas Association ("OOGA"), Oklahoma Independent Petroleum Association ("OIPA"), Pennsylvania Independent Oil & Gas Association ("PIOGA"), Texas Alliance of Energy Producers ("Texas Alliance"), Texas Independent Producers & Royalty Owners Association ("TIPRO"), and West Virginia Oil and Natural Gas Association ("WVONGA") (collectively, "Independent Producers"). The Independent Producers have participated individually or through the Independent Producers in most, if not all, of the rulemakings and associated litigation since the Environmental Protection Agency ("EPA" or "Agency") proposed to revise the New Source Performance Standards ("NSPS") for the Oil and Natural Gas Sector in August 2011. 76 Fed. Reg. 52,738 (Aug. 23, 2011).¹ While many of the Independent Producers represent companies that engage in large volume hydraulic fracturing with horizontal legs, often referred to as

¹ As the EPA has opened a new docket for the Reconsideration Rulemaking, the Independent Producers incorporate by reference their Comments on the previous rulemakings associated with 40 C.F.R. Part 60, Subpart OOOO and Subpart OOOOa, including but not limited to the following documents: EPA-HQ-OAR-2010-0505-4216, EPA-HQ-OAR-2010-0505-4626, EPA-HQ-OAR-2010-0505-4752, EPA-HQ-OAR-2010-0505-4767, EPA-HQ-OAR-2010-0505-7001, EPA-HQ-OAR-2010-0505-7685, and EPA-HQ-OAR-2010-0505-12337.

unconventional drilling, a significant portion of their membership is comprised of smaller, family run operations that engage in some form of hydraulic fracturing, involving vertical wells without horizontal legs, referred to as conventional oil or gas wells. Many of the individual members constitute as small businesses under the Small Business Regulatory Enforcement Fairness Act of 1996. From the beginning of these rulemakings, the Independent Producers have tried to illustrate to the EPA that their "one-size-fits-all" approach to regulating this industry is a) inappropriate and b) disproportionately impacts conventional operations and small businesses.

Other than the proposed revisions to requirements primarily associated with low production wells, storage vessels, and alternative methods of emissions limitations ("AMEL")/emerging technology, the Independent Producers generally support the proposed revisions in the Reconsideration Rulemaking and appreciate the EPA's effort to improve and to tailor 40 C.F.R. Part 60, Subpart OOOOa ("Subpart OOOOa") to reduce the impact on the Independent Producers and their individual members while still providing more than adequate protection of the environment. The EPA should not lose sight of the simple and somewhat unique fact that what the Agency and some stakeholders view as a pollutant is the Independent Producers' product. The members of the Independent Producers have a pure economic motivation to capture every molecule of methane possible and avoid waste.

D. AMEL – State Equivalency	2
E. Recordkeeping and Recording	2
F. Definition of Modification	3
II. <u>LOW PRODUCTION WELLS</u>	3
A. Subpart OOOOa Regulations Need to be put in Context	3
1. <u>Natural gas and oil production methane emissions are about 1.2 percent of the 2016 GHG Reporting data</u>	3
2. <u>Production methane emissions are declining as production is increasing</u>	4
3. <u>This trend will continue as new sources built since 2011 with low emissions technologies mature and displace older wells, but the regulatory proposal does not address its impact on the existing wells that would be captured in the regulations despite the declining emissions from the oil and natural gas production sector</u>	5
B. The EPA Should Provide for a Low Production Well Distinction within Subpart OOOOa.	8
1. <u>The EPA's proposed low production well provisions are inappropriate</u>	8
a. <i>The EPA fails to recognize that wells ultimately become low production wells and many wells begin as low production wells. This changes the cost effectiveness of its regulations</i>	8
b. <i>The EPA needs to provide an alternative approach for low production wells rather than a one time, ineffective assessment of a low production well</i>	11
c. <i>A low production well is a low production well – regardless of when the well is drilled</i>	12

C. The EPA's Information on Low Production Wells is Inadequate to Develop Regulations.....	14
1. <u>There are approximately 770,000 low production wells in the United States; the EPA is basing its model plant and emissions assessment on about 25 low production wells in one basin</u>	14
2. <u>The EPA's source documents on low production wells are critically flawed</u>	15
a. <i>The Environmental Defense Fund's Super-Emitters Study is specious</i>	15
b. <i>The EDF 5-Study Report is flawed</i>	18
c. <i>Fort Worth Study data is highly questionable</i>	26
d. <i>Use of 1995 emissions factors raises issues of accuracy</i>	27
3. <u>The EPA's Model Low Production Well needs improvement</u>	27
a. <i>The model plant is dominated by two elements – valves and storage vessels</i>	28
b. <i>Industry information from across the country shows different equipment counts that dispute the model well which is primarily based on the Fort Worth Study</i>	31
i. <u>Number of valves is well below model plant; wellhead assumption is too high</u>	31
c. <i>EPA model plant calculations attribute 80 percent of low production natural gas wells to valves (63 percent) and thief hatches (18 percent) and 85 percent of low production oil wells to valves (38 percent) and thief hatches (48 percent). These calculations are based on questionable emissions factors</i>	33
i. <u>If these assumptions are incorrect, it significantly changes the cost effectiveness assumptions of the EPA fugitive emissions program</u>	34
d. <i>Assessing the cost impact on low production wells needs to look beyond the common tests of cost effectiveness in a cost per ton of reduced emissions to address the cost impact in the profitability of these small wells</i>	34
4. <u>The DOE has announced a research program to determine more accurate assessments of low production well emissions</u>	36

5. <u>The EPA should make the following changes to the low production well regulations</u>	37
6. <u>The EPA should exempt booster compressors associated with low production wells</u>	38
III. <u>SUBPART OOOOa STORAGE TANKS</u>	39
A. Background/Proposal	39
B. Maximum Average Daily Throughput and Averaging Emissions Across Tank Batteries	40
1. <u>The EPA's proposal to prohibit averaging of throughput across tank batteries inappropriately ignores fundamental operational processes</u>	41
2. <u>The EPA's proposal to eliminate averaging is inconsistent with recent consent decrees related to the design and operation of vapor control systems on storage tanks</u>	43
C. The EPA's Concern About the Amount of Storage Vessels Subject to Subpart OOOOa is Overstated and Unfounded	43
D. The EPA's Proposal to Calculate Individual Tank Emissions Based Upon Throughput to Each Individual Tank is Technically Flawed and Overly Burdensome	45
E. The EPA's Proposed Methodology Could Produce the Absurd Result that Only One Tank in a Manifolded Series of Tanks is Subject to Subpart OOOOa	46
F. The EPA's Proposal to Only Include Days in Which Tanks Received Production Would Overstate Potential Emissions and Would Create an Unnecessary and Overly Burdensome Recordkeeping Requirement	47
G. The EPA Cannot Apply its Proposed Amendments Retroactively	48

A. The EPA's Assumptions Associated with Refracturing a Well Does Not Justify Abandoning a Demonstrated Emissions Increase	69
B. The EPA Acknowledged its Logical Inconsistency but has Failed to Justify Such Inconsistency	71
VIII. <u>CONCLUSIONS</u>	72

I. EXECUTIVE SUMMARY

A. Low Production Wells

- The EPA should retain provisions for low production wells. A fugitive emissions program designed for high production wells is inappropriate for low production wells
- The EPA should provide an alternative regulatory structure for all wells that become low production wells. As wells become low production wells, they are no different from wells that begin as low production wells.
- The EPA should use the Tax Code definition of "stripper well property" as its low production well definition to avoid confusion and challenges to its definition.
- The EPA should defer any fugitive emissions regulations of low production wells until it obtains information on emissions from low production wells. Specifically, the EPA should first determine whether a low production well program is appropriate and cost-effective, and then design a program based on accurate emissions information from low production wells. The Department of Energy ("DOE") is initiating a research effort to provide specific low production well emissions information that can inform these decisions and actions.
- The EPA should exempt booster compressors associated with low production wells from the current compressor fugitive emissions program requirements and incorporate them into whatever low production well program decisions it makes.

B. Storage Vessels

- The EPA's proposal to prohibit averaging of throughput across tank batteries inappropriately ignores the relevant process unit and is inconsistent with recent consent decrees related to the design and operation of vapor control systems on storage tanks/vessels.
- The EPA's concern about the amount of storage vessels subject to Subpart OOOOa is overstated and unfounded.
- The EPA's proposal to calculate individual tank emissions based upon throughput to each individual tank is technically flawed and overly burdensome.
- The EPA's proposed revisions to what constitutes "legally and practically enforceable limits" is unnecessary and arbitrarily interferes with the Clean Air Act's ("CAA" or "Act") cooperative federalism where the states are to take the lead on implementation.

C. AMEL – Emerging Technology

- The Independent Producers support the options in the Proposed Revisions to use modeling, to test technologies in a controlled test environment, and to allow manufactures/vendors to apply for approvals.
- The EPA should allow for basin-wide approvals of emerging technology for use in complying with the leak detection and repair ("LDAR") requirements in the rule.
 - The EPA can establish clear and consistent parameters under which a technology will be able to detect methane emissions and site specific variables can be addressed in conditions required for the use of the technology.
 - Basin-wide data is necessary to determine equivalency and receive approval per CAA 111(h); basin-wide surveys that can identify potential fat-tail emission sources faster and per the EPA, higher mass emission reductions from large leaks, found earlier, are offset by some degree by smaller leaks which go undetected.
 - Common sense dictates basin-level approval; the 111(h) notice and comment process required to achieve approval is very onerous and not feasible to do for every single well site.
 - CAA Sec. 111(h)(3) does not constrain basin-wide approvals.

D. AMEL – State Equivalency

- Per cooperative federalism, the EPA should recognize the approved state programs as wholly equivalent to 40 C.F.R. Part 60, Subpart OOOO's ("Subpart OOOO") LDAR program and fully delegate the implementation of the LDAR monitoring provisions to these respective states.
- Alternatively, the EPA could require the fugitive emissions component definition from Subpart OOOOa to be used when following an alternative approved state program but the EPA should not require a duplicative administrative burden; to do so would be an undue burden with no corresponding environmental benefit.

E. Recordkeeping and Reporting

- While the Independent Producers suggest additional revisions to the frequency of the fugitive emissions monitoring surveys, the proposed changes are likely to be the most beneficial change for industry, while having no detriment to the environment.

- The EPA continues to underestimate and underappreciate the burden on the industry, especially small business, associated with recordkeeping and recording that serves no environmental benefit, *e.g.*, compliance assurance.

F. Definition of Modification

- The EPA's assumptions associated with emissions increases resulting from refracturing wells are unwarranted and unsupported.
- If the EPA persists with defining a refracture as a modification; operators should be able to demonstrate, pre-fracture, that the system is tight and therefore the refracture does not automatically constitute a modification.

II. LOW PRODUCTION WELLS

A. Subpart OOOOa Regulations Need to be put in Context.

The EPA has promulgated during the past decade a number of regulations that are global climate related. Some of these are active; others are being reconsidered. For the oil and natural gas production industry, the two of greatest interest are Subpart OOOO in 2012 and Subpart OOOOa in 2016. While the initial Subpart OOOO regulation was volatile organic compound ("VOC") based, it also reduces methane because VOC and methane are produced and, therefore, emitting together. Subpart OOOO addressed the larger emissions sources related to oil and natural gas production including Reduced Emissions Completions ("RECs") for hydraulically fractured natural gas wells, pneumatic controllers, and storage vessels. Its successor regulation – Subpart OOOOa – addressed a second tier of emissions including RECs for hydraulically fractured oil wells, pneumatic pumps, and fugitive emissions. The current proposed revisions to Subpart OOOOa fine tune these prior regulations to address issues where those prior actions are excessive or need a better structure. However, all of these regulations must be put in the larger context of climate – of greenhouse gases ("GHG") emissions.

1. Natural gas and oil production methane emissions are about 1.2 percent of the 2016 GHG Reporting data.

According to 2016 EPA GHG Reporting data, methane emissions from oil and natural gas exploration and production are 1.22 percent of total U.S. GHG emissions. However, even these estimates may be overstating oil and natural gas production emissions. Most of the emissions calculations are based on emissions factors that come from analyses done in the mid-1990s. Newer analyses call into question a number of these emissions factors. A number of these inaccurate factors are also used in developing emissions tables for the regulatory proposals.

in the revisions to Subpart OOOOa. These will be addressed more specifically later in these comments.

2. Production methane emissions are declining as production is increasing.

More importantly, these methane emissions are declining as oil and natural gas production is increasing. From 2007 through 2016, U.S. shale gas production grew over 1,300 percent,² while methane emissions have declined.

More recently these trends continue, as reported in the Energy In Depth ("EID")³ blog below. Later data supports the previous results.

U.S. Oil and Natural Gas Methane Emissions Decline in 2017 as Production Increases

Source: U.S. Environmental Protection Agency Greenhouse Gas Reporting Program and the U.S. Energy Information Administration.

New EPA data showing the United States continued to lead the world in greenhouse gas (GHG) emission reductions in 2017 – a trend largely attributable to increased natural gas use – got quite a bit of attention last week.

² U.S. Energy Information Administration, available at http://www.eia.gov/dnav/ng/hist/res_epg0_r5302_nus_bcfa.htm.

³ Energy In Depth is a project funded by the Independent Petroleum Association of America, a member of the Independent Producers.

But largely overlooked was the fact that the same Greenhouse Gas Reporting Program (GHGRP) data also show that petroleum and natural gas system methane emissions from reporting facilities declined eight percent from 2016 to 2017.

Specifically, the data show methane emissions from large oil and natural gas facilities declined eight million metric CO₂ equivalent in 2017. These reductions came at the same time oil and natural gas production increased six percent (521,000 barrels per day) and three percent (700 million cubic feet per day), respectively, from 2016 levels.

These trends prove once again that the U.S. oil and natural gas industry is effectively reducing methane emissions even as record-shattering production has made the United States the world's leading oil and gas producer.

3. This trend will continue as new sources built since 2011 with low emissions technologies mature and displace older wells, but the regulatory proposal does not address its impact on the existing wells that would be captured in the regulations despite the declining emissions from the oil and natural gas production sector.

Moreover, because of the nature of oil and natural gas production, the application of controls on new sources will achieve the emissions reductions objectives without the need to create extensive existing source regulations. Oil and natural gas production operations differ from other types of manufacturing. After the period of initial production, wells begin to decline – generally referred to as the "production decline curve." And as the production of the well declines, its ability to emit VOCs and methane into the atmosphere also declines. Emissions from these older wells will be a smaller portion of the 1.22 percent of emissions, yet the EPA's decision to regulate methane directly under Section 111(b) of the CAA subjects hundreds of thousands of existing wells to regulation. The Independent Producers assert that the application of the proposed requirements to existing sources is not effective. The regulatory burden on state and federal regulators of exposing hundreds of thousands of existing sources is completely overlooked in Subpart OOOOa and the EPA was obligated to consider the cost in promulgating Subpart OOOOa and the Proposed Revisions.

The declining nature of oil and natural gas wells also differentiates the exploration and production segment of the oil and natural gas sector from other segments further downstream where emissions remain fairly constant overtime. Ultimately, the production from the "new" wells declines to the point where they become "marginal" wells or as the proposed regulations describes them, "low production" wells. These are defined as wells that produce 15 barrels/day ("B/D") of oil or less and 90 thousand cubic feet per day ("mcf/d") or less of natural gas. Currently, there are over 1.1 million oil and natural gas wells in the United States; approximately 770,000 are marginal wells. However, these small individual wells account for about 10 percent of U.S. oil production and 11 percent of its natural gas production. Consequently, unlike manufacturing facilities where new facilities do not replace existing ones, in the oil and natural gas production industry, the implementation of technology on new wells will rapidly result in its application across the breadth of the industry as new wells become the predominant source of

emissions for the industry. This can be understood by looking at past experience as shown in the graphs below:

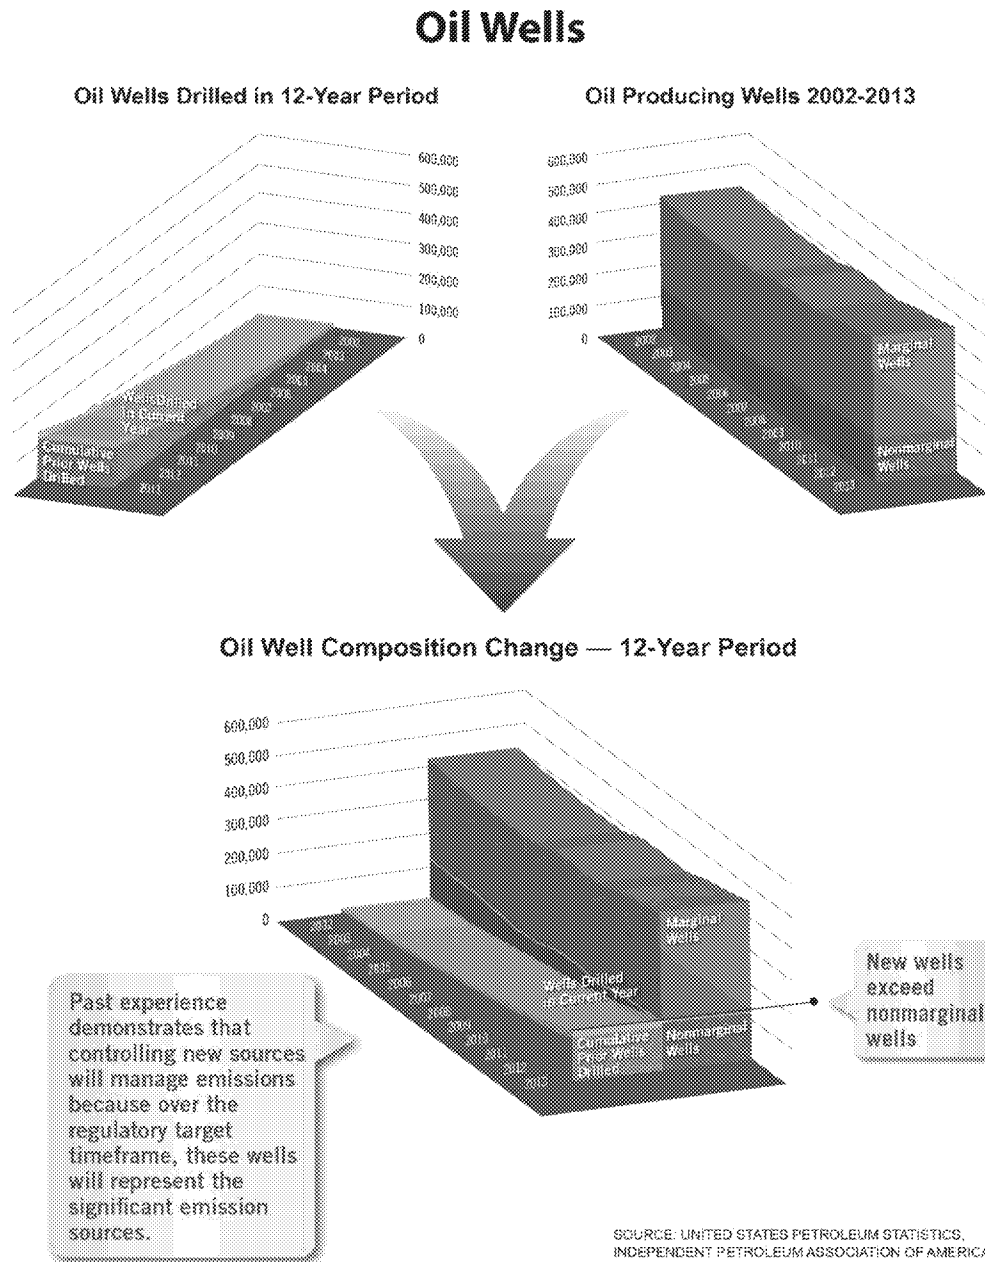

Natural Gas Wells

As this graphic demonstrates, after 12 years, wells subject to the new source regulatory requirements will dominate the production of natural gas, and the remaining wells will be marginal wells with minimal incremental emissions beyond the emissions from sources already subject to regulation. The cost associated with reducing those incremental emissions will be greater than the cost of implementing controls on new or modified sources and will likely make

many of the marginal wells uneconomic, causing them to be shut in/abandoned. The opportunity cost or value of that last production is not offset by the minimal emissions reductions achieved by regulating existing sources.

A similar pattern exists for oil wells as shown below:

While this analysis is based on past experience, if it were expanded to a 20-year period, it would show a similar trend and demonstrate that the use of new source regulations is more than adequate to address reducing methane emissions from the oil and natural gas sector, in general, and the exploration and production segment, in particular. The EPA's use of methane based regulation exposes the hundreds of thousands of existing marginal wells to regulation under

Section 111 of the CAA, and the EPA has failed to adequately account for and justify subjecting these existing exploration and production sources to such regulation.

B. The EPA Should Provide for a Low Production Well Distinction within Subpart OOOOa.

In its initial Subpart OOOOa regulatory proposal, the EPA chose to exclude low production oil and natural gas wells. The Independent Producers supported this concept because low production wells are an insignificant contribution to national methane emissions and, additionally, they cannot absorb the costs of the EPA fugitive emissions programs designed for large production wells. The economic viability of most of these wells is uncertain because of other additional state and federal requirements and low natural gas prices. However, in finalizing Subpart OOOOa, the EPA removed the low production exclusion. This is an error.

The EPA has now proposed to reinstate a low production well distinction but has not gone far enough. The proposed biennial fugitive emissions surveying for low production wells is helpful but is insufficient for three critical reasons: 1) the Independent Producers believe that with the proper studies, sampling, and testing, the low production wells will fall below reasonable emissions standards; 2) even on a biennial basis, the fugitive emissions survey requirements are not cost effective; and 3) as long as the NSPS are based on methane emissions versus emissions of VOCs, hundreds of thousands of existing wells will be exposed to unnecessary controls and costs.

1. The EPA's proposed low production well provisions are inappropriate.

- a. The EPA fails to recognize that wells ultimately become low production wells and many wells begin as low production wells. This changes the cost effectiveness of its regulations.*

While Subpart OOOOa primarily addresses new sources, it fails to recognize the preeminent reality of oil and natural gas production – all wells deplete and decline in production over time. The reality of oil and natural gas well depletion has been well recognized since oil and natural gas production began. The 1940 book, This Fascinating Oil Business, includes this description:

... The production of all wells in which gas is the chief expulsive force and which are produced to capacity declines rather rapidly. This decline is especially noticeable in the early stages, from the "initial production" through what is known as the "flush" period and is less noticeable after the "flush production" is gone and the well is on "settled production," but the decline continues just the same.

If the well is producing at capacity the decline is quickly noticeable; if it came in at two thousand barrels a day, in six months it may be down to a thousand barrels and in a year to six hundred. If the well is allowed to produce only a part of its potential production the decline may not be noticeable for a long time; the decline in pressure will be slower, for one thing, and for another, a well allowed to produce only twenty barrels a day will probably behave much the same whether its full productive capacity is two thousand barrels or only two hundred. Sooner

or later, however, the well will fail to make the twenty barrels or one hundred or whatever amount it has theretofore been producing, and from that time on its decline will be apparent. Unless it goes to water the well may produce for twenty or fifty or even seventy years, but each year it will produce less than the year before.

Fields and individual wells vary greatly, but in general this year's production from a settled well produced to capacity will be from ten to thirty per cent less than last year's.⁴

Decline continues to be an integral part of oil and natural gas production, but its nature has changed. The graphic below demonstrates that unconventional wells begin as high production operations, decline rather quickly, and ultimately become low production wells.

Consequently, the EPA's determinations regarding the cost effectiveness of its fugitive emissions requirements on wells must be carefully examined. What may be a cost-effective

⁴ Ball, Max W., This Fascinating Oil Business, The Bobbs-Merrill Company, 1940, p. 142.

program for high production operations will be very different as wells decline and become low production wells.

Unfortunately, this is not a new issue, but it is an issue that the EPA has largely ignored in the Subpart OOOOa regulatory process. In March 2014, Carbon Limits released a report: Quantifying Cost-effectiveness of Systematic Leak Detection and Repair Programs Using Infrared Cameras.⁵ This report produced a particularly telling assessment of the type program included in the Subpart OOOOa regulations and in the revised proposal. Notably, the report showed that the effectiveness of these LDAR programs for wells and well sites is highly limited. The following graphic is illustrative.

Figure 1: Distribution of Project NPV (base case assumptions) per survey for different types of facilities

As the graphic demonstrates, for 80 percent of well sites, the LDAR program would create more than just an ineffective cost burden; it would create a negative net present value ("NPV"). Moreover, these results are based on natural gas prices of \$4/mcf natural gas – well above the historic prices in the U.S. marketplace.

Most of these negative NPV wells are low production wells – wells that produce less than 15 B/D which is equivalent to gas production wells of 90 mcf/d. Other experience with LDAR programs on low production wells demonstrates that the cost is excessive.

A California example is illustrative. This data comes from approximately 2,900 wells with an average production of 3.6 B/D; it includes 580,324 inspections which found 667 leaks. Using Leaker Emission Factors from 40 C.F.R. Part 98, Subpart W ("Subpart W") and assuming the leaks existed the entire quarter, the results are as follows:

Emissions Found

⁵ See Quantifying Cost-effectiveness of Systematic Leak Detection and Repair Programs Using Infrared Cameras, Carbon Limits (May 13, 2014), available at https://www.epa.gov/sites/production/files/2016-04/documents/quantifying_cost-effectiveness_leak.pdf

- 142 leaking valves at 13.9 thousand cubic feet ("mcf") per quarter ("qtr") leaker factor = 1974 mcf.
- 525 leaking connections at 12.3 mcf/qtr leaker factor = 6,457 mcf.
 - Total emissions = 8431 mcf

Cost of Recovered Gas

- The annual operating cost of LDAR equipment and crews only = \$800,000. This is a low cost compared to existing Subpart OOOOa semi-annual requirements which has an estimated cost of \$1,599/well or in this case \$4,600,000/year.
- Using a very conservative estimate of \$800,000/8413 mcf = \$95/mcf.
- At \$1,599/well the cost would be \$4.6 million = \$546/mcf.

Clearly, the cost of recovered emissions is far different than the value in the EPA's expectations. Importantly, these numbers are too low because the Emission Factor is a generic number – not one based on low producing wells. We will address this issue in more detail below.

However, the key point here is that low production wells need a program designed for their operations.

b. The EPA needs to provide an alternative approach for low production wells rather than a one time, ineffective assessment of a low production well.

In the Reconsideration Rulemaking, the EPA defines a low production well as:

well sites with average combined oil and natural gas production for the wells at the site less than 15 boe per day averaged over the first 30 days of production ("low production well sites")⁶

As stated previously, oil and natural gas wells ultimately become low production wells. And, as low production wells, they have contributed or will continue to contribute to the nation's energy supply for decades. Currently, low production oil wells account for about 10 percent of American oil production, and low production natural gas wells account for 11 percent of American natural gas production. As a result of the additional cost associated with the fugitive emission surveying requirements in the Reconsideration Rulemaking, low production wells will be prematurely shut in and plugged. The nation will lose this reliable production.

The Reconsideration Rulemaking creates two pools of fugitive emissions requirements – one annual program for large production wells and one biennial program for low production wells. Setting aside for a moment the issues of the cost effectiveness of these programs, the approach creates some absurd results. In the approach taken by the EPA in the Reconsideration

⁶ 83 Fed. Reg. 52,062.

Rulemaking, a well with production of 15 B/D after 30 days of production would be subjected to the biennial fugitive emissions program. However, a well with 18 B/D of production after 30 days would be perpetually in the annual fugitive emissions program even though it will clearly be below the 15 B/D threshold soon after its production starts.

Instead of this unworkable and unfair system, the EPA needs to craft an approach that allows wells when they begin producing less than 15 barrels of oil equivalent ("BOE") to shift to an alternative fugitive emissions program – a program based on the emissions pattern of low production wells. Such an approach would encourage the continued operation of wells as they decline but collectively provide an important component of the American oil and natural gas resource base.

Such an approach would not pose any adverse impact on the environment. First, the pool of wells producing American oil and natural gas is constantly changing. As it changes, older wells are being replaced with: 1) wells that meet the requirements of Subpart OOOO; and 2) many wells that used those technologies before Subpart OOOO as a part of the Natural Gas STAR program. Second, assuming the alternative as described above is created, a substantial portion of new wells are drilled on sites with multiple wells. Those well sites would continue to be subjected to the Subpart OOOOa fugitive emissions requirements until all of the wells became low production wells. Third, as discussed *infra*, the DOE is initiating a research program to define the emissions profile of low production wells. The EPA should use the results of that research to design an appropriate low production fugitive emissions program rather than try to shoehorn these wells into a program that was never designed for these operations.

Until then, the EPA should choose to act as it has in the October 2016 Control Techniques Guidelines ("CTG") for VOC emissions from existing oil and natural gas production facilities in ozone nonattainment regions and defer action on a low production well fugitive emissions program.

c. A Low production well is a low production well – regardless of when the well is drilled.

Characterizing wells in perpetuity based on the wells' first 30 days of production is arbitrary and unnecessary. The term "low production well" is a construct of these NSPS rulemakings but the concept or characterization of this category of wells is not new to the industry. The most recent characterization of "low production well" largely tracks commonly used approaches to defining smaller wells whether using the term low production well or marginal well or stripper well. These terms spring from the stripper well definition in the tax code. The use of the tax code definition should serve well as a definition for a "low production well" in any revisions to Subpart OOOOa that provide for regulatory actions regarding these wells. A principal issue in developing the low production well concept will be its application to each well. Inevitably, there will be challenges. Use of the tax code stripper well definition provides a long history of such determinations. It also provides a framework that is well understood by the regulated industry.

For example, one of the key issues in understanding the definition a low production well will be addressing production of both oil and natural gas which are common elements of these

wells. That is, most oil wells will have associated gas and most natural gas wells will have natural gas liquids. These issues have arisen in the determination of stripper wells, and the process to determine their status has been refined over the years.

The essence of the stripper well provisions is found in Section 613A of the Tax Code. A stripper well is defined in Subsection (c)(6)(E):

For purposes of this paragraph, the term "stripper well property" means, with respect to any calendar year, any property with respect to which the amount determined by dividing—

(i) the average daily production of domestic crude oil and domestic natural gas from producing wells on such property for such calendar year, by

(ii) the number of such wells,

is 15 barrel equivalents or less.

The calculation process to make this determination is straightforward. All production is converted to oil equivalents. To convert gas production to oil equivalents, a ratio of 6,000 cubic feet equals one barrel of oil⁷. Consequently, 90,000 cubic feet equals 15 barrels; this is the source in the low production definition that uses 15 B/D or 90 mcf/d as its basis. However, the reality of the calculation revolves around putting all production on a common basis – oil. Thus, if a well produces 10 barrels of crude oil and 12,000 cubic feet of natural gas, its equivalent barrels produced would equal 12 (*i.e.*, $10 + (12,000 / 6,000)$). This approach then resolves questions regarding how to evaluate wells with both oil and gas production.

Clearly, another issue that arises will be the application of the stripper well definition in the context of compliance assurance with Subpart OOOOa. Compliance assurance is always a significant question. But, using a known and understood criteria provides industry with a clearer standard. Most of the instances where the issue would arise is when a well declines, and this is the normal circumstance under which a well is assessed as a stripper well. The other instance that arises relates to the initial application of the regulatory requirements – in this instance the fugitive emissions monitoring program. The issue here involves the current requirements in Subpart OOOOa that the initial fugitive emissions monitoring occurs within 60 days of the startup of production, the determination of the well's status 30 days after its initial operation, and the tax code stripper well calculation that uses annual information. However, this issue could be resolved by creating some type of initial production threshold – *e.g.*, 250 B/D – that would suggest the likelihood that the well would decline to a low production well soon after its initial

⁷ Section 613A (c)(4) Daily depletable natural gas quantity.

For purposes of paragraph (1), the depletable natural gas quantity of any taxpayer for any taxable year shall be equal to 6,000 cubic feet multiplied by the number of barrels of the taxpayer's depletable oil quantity to which the taxpayer elects to have this paragraph apply. The taxpayer's depletable oil quantity for any taxable year shall be reduced by the number of barrels with respect to which an election under this paragraph applies. Such election shall be made at such time and in such manner as the Secretary shall by regulations prescribe.

operation. Wells meeting this threshold would have the initial fugitive emissions monitoring program delayed for one year. If the well did not fall below the low production well threshold by that time, the initial fugitive emissions monitoring could be required 60 days later.

Once revised Subpart OOOOa regulations address the pressing issue of providing an exclusion for low production wells and an offramp from the application of the Subpart OOOOa requirements when wells inevitably decline below the low production well threshold, the issue of interpreting the definition will clearly arise. Using the stripper well definition from the tax code brings with it a clear and certain process for determining its application. While the previously used EPA definitions of low production wells parallel the intent of the stripper well tax code definition, a new definition will lead to interpretation challenges that could be avoided.

C. The EPA's Information on Low Production Wells is Inadequate to Develop Regulations.

1. There are approximately 770,000 low production wells in the United States; the EPA is basing its model plant and emissions assessment on about 25 low production wells in one basin.

Perhaps the most significant aspect of Subpart OOOOa versus Subpart OOOO is that it is based on the regulation of methane instead of VOCs. A methane-based regulation not only addresses new and modified sources under Section 111(b), it opens the pathway to a nationwide existing source regulatory scheme under Section 111(d) of the CCA. Consequently, the scope of possible sources expands from the roughly 20,000 wells drilled annually to the 770,000 existing operating oil and natural gas wells. This is a vastly different regulatory expanse.

The EPA's approach to developing its low production well model plant ("Model Low Production Well") in the Technical Support Document ("TSD") and thereby its assessment of the effectiveness of a fugitive emissions program — returns to a fundamental question of the EPA's responsibility and obligation to develop its own data needed for regulatory actions. The data relied upon in the Reconsideration Rulemaking is wholly inadequate.

There are approximately 771,000 low production (marginal) wells in the United States — 394,000 oil wells, 377,000 natural gas wells. These wells are spread across over 30 states. The EPA's reliance on approximately 25 potentially low production wells in one play—the Barnett Shale in Texas — to define its Model Low Production Well is inadequate. This action is flawed for several reasons. First, there is no reason to believe that the Barnett Shale is representative of all low production wells in various plays across the country. Second, the data that was collected in the Fort Worth Study was not intended to address low production wells specifically and is simply a subset of wells incidental to a larger study. Third, even this well selection appears flawed; some wells do not appear to be low production wells. Fourth, and perhaps most importantly, trying to establish a Model Low Production Well on the basis of 25 single basin wells will lead to ineffective results and unproductive, inefficient use of resources

The same issue arises in the emissions analyses by various "Keep It in the Ground" environmental groups. The most prominent of these efforts relies on results from one or two basins, and the low production well data is an unintended subset of the larger study. That is,

when the studies are made, there is no understanding of the production from the well. Afterwards, the analyses sort the data based on production, and some subset is low production wells. Even the larger compilations of these studies will include an accidental collection of less than 200 low production wells from one or two basins which is not the appropriate basis for developing national regulatory requirements impacting hundreds of thousands of wells.

2. The EPA's source documents on low production wells are critically flawed.

The flaws in the analyses by the EPA and Keep It in the Ground environmental groups that want to influence the EPA's decisions can be seen in a number of actions.

a. The Environmental Defense Fund's Super-Emitters Study is specious.

The Environmental Defense Fund's data manipulation in the study it submitted to the 2015 Subpart OOOOa rulemaking proposal distorts the role of low producing wells regarding methane emissions ("2015 EDF Study"). This study was then characterized as the basis for removing the low producing well exclusion for the Subpart OOOOa fugitive emissions program initially proposed by the EPA.

It is important to understand that the 2015 EDF Study used data from a number of different studies to create its arguments. All of the underlying studies generated their data by driving vehicles with samplers downwind of production sites, hunting for methane plumes. None of them used samples taken on the production site. This creates two issues. First, it measures everything emitted at the site – fugitive emissions and permitted vents. Second, the data are collected over minutes – maybe over an hour – but not over a day. The data in the study are presented as if they were daily emissions, but the studies merely scale up hourly estimates. Consequently, emissions that might occur for several hours, but not the full day, would be overstated.

Before turning further to describe the submitted study, it is useful to look at the same data using a direct graph of emissions. In this graph, marginal wells are those with production volumes of 90 mcf/d or less – the EPA definition of low production wells.

This graph is consistent with information from other studies showing that a small portion of wells have an emission profile for some reason with high emissions while most wells have really low emissions. Importantly, it also clearly shows that low production wells have far smaller emissions. But, since this graph is using the same data as the study, it could also be overstating emissions because of scaling short-term emissions to a daily amount.

With this background, turning to the presentation of the same material in the study demonstrates how it was manipulated. Below is the graphic used to present the data. It would suggest that the worst emitting operations – the "super-emitters" – are the smallest wells (the

orange line and the blue line, circled in green). Having directly plotted this data, the obvious issue is how such a result can occur.

It is a busy and confusing graph – it is intended to be. The study uses data analysis tricks to create the appearance that low production wells are "super-emitters."

First, it shows emissions as a percentage of production rather than actual emissions. Thus, one mcf emitted out of ten mcf produced is 10 percent, but 50 mcf emitted out of 1,000 mcf produced is five percent. As a result, it skews the perception of the data to imply that low production wells are large emitters when they are not.

Second, its production volumes are really sales volumes, not the amount extracted from the wellhead. Consequently, a "proportional loss rate" of 50 percent would be the calculated loss divided by the volume sold. If the percentage of loss was calculated based on extracted volumes, the 50 percent "proportional loss rate" would drop to 33 percent because the loss would be added to the sales volume to obtain the extracted volume.

Third, it only shows data from the 70th percentile of information. This excludes all of the virtually zero emissions that dominate the data.

Fourth, it uses a logarithmic scale to present the data. One of the reasons to use logarithmic scales is to flatten curves to make them look more like straight lines.

The EPA should not have relied on such a specious report to make a regulatory decision with profound effects on the future of American oil and natural gas production.

b. The EDF 5-Study report is equally flawed.

In May 2018, EDF released another methane emissions study ("2018 EDF Study") that it heralded as another example describing the underestimation of national methane emissions and demanding more federal regulation. It is as specious as the 2015 EDF Study and should be given no import by the EPA in assessing regulatory options. Following is a discussion of its key failings.

To put this discussion in context, the EID addressed the 2018 EDF Study.⁸ Its analysis follows:

The Environmental Defense Fund (EDF) has released a myriad of studies on natural gas system methane emissions over the past six years that have found low leakage rates between 1.2 and 1.5 percent of production. Five such studies are featured in the following EID graphic.

So the fact that a new EDF study released today finds methane leakage rates of 2.3 percent — well above what EDF-led research has previously found and "60 percent higher than the U.S. EPA inventory estimate," according to the report — begs the question: What changed with regard to EDF's methodology for this study that yielded a much higher leakage estimate than its past research has shown?

⁸ Whitehead, Seth, [Five Things to Know About New EDF Methane Study](https://www.energyindepth.org/five-things-to-know-about-new-edf-methane-study/), Energy in Depth (June 21, 2018), <https://www.energyindepth.org/five-things-to-know-about-new-edf-methane-study/>

Turns out, quite a lot changed, and most of the changes raise red flags regarding the study's conclusions. Not only did the authors of the new EDF study — which includes no new measurements and instead calculates national methane emissions based on past studies — opt not to use past EDF research as a basis for their emissions calculations, it relies exclusively on five far less comprehensive facility-level studies that lacked industry participation to arrive at its conclusion of higher U.S. emissions than previously reported. In contrast, an "alternative" calculation, based partially on EDF's past studies, that finds emissions in line with current EPA estimates is buried in the study's supplemental data and is not even mentioned in the report.

These are just two of several key issues regarding the manner in which EDF conducted this study that appear aimed at producing the most extreme emissions estimate possible ahead of the 27th annual World Gas Conference (WGC), which begins Monday in Washington, DC. Here is a deeper look at each issue.

#1. Exclusive Use of Facility-Scale Study Data Goes Against National Academy of Sciences' Recommendations and Likely Exaggerates Emissions

This study's national methane emissions estimate is based entirely on downwind, facility-based studies. From the report:

"In this work we integrate the results of recent facility-scale BU studies to estimate CH₄ emissions from the U.S. O/NG supply chain, and then we validate the results using the TD [top-down] studies."

However, a recent National Academy of Sciences (NAS) report aimed at improving national methane emissions inventories recommends a more comprehensive approach combining "bottom-up" measurements — both of the component- and facility-level variety — along with "top-down" measurements:

*"Coordinated, contemporaneous top-down and bottom-up measurement campaigns, conducted in a variety of source regions for anthropogenic methane emissions, **are crucial for identifying knowledge gaps and prioritizing emission inventory improvements.** Careful evaluation of such data for use in national methane inventories is necessary to ensure representativeness of annual average assessments."*

EDF has conducted studies combining the comprehensive top-down/bottom-up methods recommended by NAS before. Zavala-Araiza et al. is the most notable example, and that study found a methane leakage rate of just 1.5 percent. Just as notably, a recent National Energy Technology Laboratory study based on Zavala-Araiza et al. data estimates national methane emissions at 1.65 percent. That report involved several of the co-authors of this most recent EDF study that reached much different conclusions.

The new EDF report argues that using facility-level measurements exclusively is appropriate because component-based studies can "under-sample abnormal operating conditions" such as malfunctions and large leaks. But this rationale ignores flaws with facility-level measurements that can lead to overestimation of emissions. For instance, facility-level measurements can capture episodic emissions, such as liquids unloading,

and inaccurately characterize them as normal emissions that would be occurring 24 hours a day, seven days a week. The latter issue can be exacerbated when researchers lack a fundamental understanding of the facilities where they are taking measurements, which brings us to the next major issue with the study.

#2. Lack of Industry Collaboration Goes Against National Academy of Sciences' Recommendations

With regard to the ground-based, facility-level studies used as the basis for estimating national emissions in this report, the report's supplementary information document notes:

*"Sites were reported to be sampled on a quasi-random basis **without advance operator knowledge.**"*

Not only does EDF admit that some of the studies used did not conduct truly random sampling, it admits that industry wasn't involved in these studies on any level. This again flies in the face of recommendations made in the NAS report, which states:

"[V]erifiability is the bedrock upon which inventories should be built if they are to be widely applicable to policy needs."

The lack of industry participation is surprising, considering EDF's past methane research is well known to have been a collaborative effort between EDF, academia and industry, a fact EDF has frequently touted. But even more surprising is EDF's justification for excluding industry from participating in this particular study. From the report:

*"Operator cooperation is required to obtain site access for emission measurements. Operators with lower-emitting sites are plausibly more likely to cooperate in such studies, and workers are likely to be more careful to avoid errors or fix problems when measurement teams are on site or about to arrive. The **potential bias** due to this 'opt-in' study design is very challenging to determine. We therefore rely primarily on site-level, downwind measurement methods with **limited or no operator forewarning** to construct our BU estimate."*

Not only does EDF fail to provide a single reference to back up this claim of "potential bias" that it claims necessitated it to use the methodology highlighted above, but none of the five co-authors of this report, who were also the lead authors of past EDF methane research that was conducted in close concert with industry, have ever publicly claimed any "bias" whatsoever. Not once.

EDF's assertion appears to be purely speculative in nature and also appears to be an excuse to use these studies as a basis for exaggerated national emission estimates.

#3. "Alternative" Emissions Estimate That Is In Line With EPA Greenhouse Gas Inventory (And Past EDF Research) Is Not Included In Report

In the supplemental materials document for this report, EDF includes the following "alternative" national emissions estimates based on source-based reports, several of which are past EDF studies.

Source: Table S3	GHGI	Source-based EDF estimate (Gg CH ₄ /yr) – Alternative EDF estimate	Site-based estimate (Gg CH ₄ /yr) – Primary Method
Total U.S. Oil and Gas Supply Chain	8,100 (6,800 – 10,000)	8,800 (8,400 - 9,700)	13,000 (12,000 - 15,000)

Source: Alvarez et al. supplementary materials

This "alternative" estimate finds the national methane leakage rate is 1.4 percent, which (not surprisingly) not only aligns with past EDF studies, but also the EPA Greenhouse Gas Inventory.

Remarkably, the data from this "alternative" estimate isn't mentioned at all in the actual report, even though EDF notes that an extensive list of source-based studies featured in the supplemental data of the report has "dramatically improved understanding of the sources and magnitude of CH₄ emissions from the industry's operations."

EDF also argues that its "primary" estimate — which, again, is based solely on facility-level studies — is in line with aggregate average emissions found in the following nine "top-down" studies based on emission measurements largely collected via aircraft measurements.

"When the BU estimate is developed in this manner, direct comparison of BU and TD estimates of CH₄ emissions in the nine basins for which TD measurements have been reported indicates agreement between methods..."

Table S2. Reported estimates of O/NG CH₄ emissions from aircraft-based top-down (TD) studies, listed in decreasing order of natural gas production. Italicized values were calculated in this work; shaded rows indicate a second independent, statistically consistent set of reported measurements in two basins (not used directly in this work in favor of the more recent results based on more intensive sampling). Uncertainties are 2-sigma values calculated from reported uncertainties.

‡ Methane emitted normalized by methane produced

§ Production weighted

Source: Alvarez et al. supplementary materials

But this claim is a stretch on a couple levels. First, the cumulative data from the above "top-down" studies show a national leakage rate of 1.8 percent, well below the 2.3 percent leakage rate this new EDF study claims. Though that is within the study's .5 percent uncertainty range, top-down studies typically overestimate oil and gas methane emissions due to the fact that emissions measurements from such studies are difficult to attribute to specific sources.

In other words, it is highly implausible that "bottom-up" methane emissions estimates would be higher than "top-down" estimates.

And in fact, a recent National Oceanic Administration (NOAA) study finds that top-down studies have likely overestimated emissions by mischaracterizing episodic emissions as normal emissions. Such emissions can also be detected and mischaracterized via facility-level measurements. So it's not surprising that this EDF study tries to discredit that NOAA study.

#4. Attempts to Discredit Study That Finds Misrepresentation of Episodic Events Can Lead to Inflated Emissions Estimates Via Daytime Bias

Another factor that can lead to facility-scale measurements overestimating actual normal emissions is the fact that such methods are conducted in the daytime and, thus, can capture emissions from episodic events – such as liquids unloading – that are conducted during the day and inaccurately extrapolate them as if they are constant. This fact was further confirmed by a recent peer-reviewed NOAA study of the Fayetteville Shale covered by EID last year.

Perhaps anticipating that 2017 study would be used to call this new EDF report's conclusions into question, EDF attempts to discredit the NOAA study in the paper:

"[W]e consider unlikely an alternative hypothesis that systemically higher emissions during day-time sampling cause a high bias in TD methods."

"[T]here is no reason to expect daytime bias in the kinds of abnormal operating conditions that are thought to characterize high-emitting production (and gathering) sites, which operate continuously. In fact, it is plausible that abnormal emissions could actually be higher at night because they are less likely to be found and corrected in the absence of operators."

The above claim is directly contradicted by the following, which acknowledges the validity of the NOAA Fayetteville study, but claims it isn't relevant to other basins.

"O/NG emissions are systematically higher during daytime hours when TD and BU measurements have been made, and lower at night. This situation was reported for the Fayetteville Shale but appears to be unique because the effect is caused by manual liquids unloadings, which represent a much higher fraction of total production emissions than in any other basin."

The fact is, events such as liquid unloadings are common in other basins and downwind measurements, such as the ones used as the basis for this EDF analysis, do tend to be higher because they are conducted during the day.

#5. Despite EDF's Alarmist Characterizations, Natural Gas' Climate Benefits Remain Clear

The report claims the oil and natural gas development emissions level estimated in this report combined with carbon emissions from current natural gas combustion is having the same climate impact as coal in the short term (20-year timespan):

*"Indeed, our estimate of CH₄ emissions across the supply chain, per unit of gas consumed, results in roughly the same radiative forcing as does the CO₂ from combustion of natural gas over a 20-year time horizon (31% over 100 years). Moreover, **the climate impact of 13 Tg CH₄/y over a 20-year time horizon roughly equals that from the annual CO₂ emissions from all U.S. coal-fired power plants operating in 2016 (31% of the impact over a 100-year time horizon).**"*

But as alarming as that claim might be, it is essential to note that natural gas maintains clear climate benefits over other traditional sources even at much higher leakage rates than purported by this study.

A recent hydraulic fracturing issues brief published by Washington D.C.-based environmental think tank Resources for the Future (RFF) notes:

"If more than about 4% of the natural gas produced in the United States is emitted as methane (rather than being burned), the climate benefits of gas's displacement of coal

disappears over a 20-year time frame. If the time frame is 100 years, the leakage rate would have to be more than 8% for natural gas to be a climate loser relative to coal."

The following International Energy Agency (IEA) graphic illustrates RFF's point, showing natural gas maintains its climate benefits even at high leakage rates and regardless of time-frame considered.

Greenhouse-gas emission intensity of natural gas compared with coal
IEA analysis

GWP20 = global warming potential over a 20-year timeframe

GWP100 = global warming potential over a 100-year timeframe, based on the ranges from the Fifth IPCC Assessment Report (IPCC, 2014)

Conclusion

This EDF study spends an inordinate amount of time explaining why its conclusions are plausible rather than explaining how it reached its conclusions. And it's clear why — once one digs into the report's supplemental information, it's clear that the conclusions are based on some pretty shaky assumptions and speculation that runs counter to established and/or recommended best practices for such research.

But at the end of the day, the EDF study is not only an outlier in terms of the overall body of current methane research — it's also an outlier with regard to EDF's collective methane research, which has consistently found leakage rates between 1.2 and 1.5 percent. In the meantime, EPA data show oil and gas methane emissions have declined 14 percent since 1990 even as oil and natural gas production have skyrocketed. Combined with the fact that increased natural gas use has helped contribute to the best air quality of the modern era and the lowest carbon emissions in 25 years, it is clear that the shale revolution has been a win-win for the economy and environment.

As EID described above, the EDF developed no new data; it used data from other studies. These included some of the same data from the EDF's earlier specious "Super Emitters" report. Unsurprisingly, plotting the data from this study follows the same pattern as other studies,

including low production wells having a much lower final emissions point than larger wells. But, this reality does not prevent EDF from casting unwarranted allegations about low production wells.

Correspondingly, the EDF report builds its conclusions on the same flawed underlying information. Because the collected data on emissions comes from short-term, remote monitoring (drive by monitoring), it inherently means that (1) the emissions information cannot distinguish between permitted emissions like storage tank vents and equipment leaks, (2) it cannot distinguish daily emissions from short-term sporadic emissions due to maintenance activities, and (3) it is skewed toward overestimating emissions by converting these short-term measurements into daily emissions rates. The 2018 EDF Study is inaccurate and unreliable.

The EDF's biases are reflected in other aspects of its report. For example, in the report, the authors make the following observations related to "top down" data collections:

Notably, the two largest sources of aggregate emissions in the EPA GHGI – pneumatic controllers and equipment leaks – were never observed from these aerial surveys.

A true analyst might have assessed this information and asked some probing questions. For example, if these sources were not shown as substantial emissions, could that mean that the EPA Inventory of U.S. Greenhouse Gas Emissions and Sinks ("GHGI") emissions factors were overstating the emissions? Other studies have suggested that the EPA emissions factors for certain types of pneumatic controllers that are widely used at production sites are overestimating emissions by a factor of 100^{9,10}. Various studies evaluating fugitive emissions programs have suggested that the expectations of reductions from these programs are significantly overstated¹¹. Did these analysts consider the import of these data? Of course not. They noted it in passing and used the EPA GHGI emissions factors in calculating their "bottom up" site-based emissions estimates.

It is somewhat difficult to follow the convoluted path that the EDF takes to generate its excessively high emissions estimates. What is clear is that the EDF devises a series of assumptions to argue that emissions are related directly to natural gas production. At least for oil and natural gas production, this conclusion runs directly contrary to all other assessments that have shown methane emissions falling as production increases — results that are in part due to voluntary actions and in part to regulatory requirements such as Subpart OOOO.

⁹ Whitehead, Sean, New EPA Study Indicates Agency Is Greatly Exaggerating Methane Emissions, Energy In Depth (May 8, 2017), <https://www.energyindepth.org/new-epa-study-indicates-agency-greatly-exaggerating-methane-emissions/>

¹⁰ Oklahoma Independent Petroleum Association, Pneumatic Controller Emissions from a Sample of 172 Production Facilities (November 2014), https://www.oipa.com/page_images/1418911081.pdf

¹¹ Whitehead, Seth, New Study Challenges Claim That Methane Emissions From Oil and Gas Are Higher Than EPA Estimates, Energy In Depth Climate & Environment (October 29, 2018), <https://eidclimate.org/study-challenges-methane-oil-gas-cpa/>

This approach yields some specific, highly questionable results, including a conclusion that 26 to 30 percent of methane emissions result from natural gas and oil wells with production rates at or below 10 mcf/d. This includes calculated emissions estimates derived from the mathematical assumptions in the studies for wells where no data existed. For these small wells with emissions, the EDF bases its determinations on escalating short-term data – emissions during an hour or less – into daily rates from less than 30 natural gas wells.

This EDF Study, like its predecessors, suffers from the same underlying intent. Its purpose is to distort the perception of success in understanding methane emissions and the efforts to reduce them. Its purpose is to drive new regulations — particularly regulations of low production wells, new, modified and existing. The EPA should not accept or rely upon such flawed data for making regulatory decisions.

c. Fort Worth Study data is highly questionable.

The EPA relies heavily on data from a study in Fort Worth, Texas, on wells in the Barnett Shale formation. Unlike most studies, this one was conducted with the cooperation of natural gas producers and included facility information. While the emissions data was taken by offsite mobile sampling for short time periods like the other emissions data referenced in the EDF studies, detailed production site information was provided. The EPA relies on this information to develop its Model Low Production Well. However, like all other studies, the Fort Worth study collected data broadly, capturing both low production wells and large wells. Low production wells were not specifically targeted or defined at the time of the data collection.

The EPA has now apparently extracted from the larger data base those wells with production at or below its 90 mcf/d low production well threshold. It includes 25 dry gas wells and two wet gas wells. However, a closer examination of this data demonstrates key flaws. These flaws are important because the selected wells then shape the model facility. The model facility then becomes the basis for the low production well emissions estimates that then justify the requirements for the fugitive emissions program.

For example, of the 25 dry gas wells, eleven wells show no production at the time that the emissions data was taken. The consequence of including the wells with zero or less than one mcf/d is the impact on the number of pieces of equipment at a site that then becomes the basis of the model facility and the basis for emissions estimates from these wells. For example, the number of valves at a site drives valve emissions which are a significant factor in the total low production model facility emissions calculations. With all 25 sites in the calculation, the EPA generates an average valve number of 108. However, if the zero and less than one mcf/d wells are removed, the average valve number drops to 75. Similarly, the number of tanks per well site drops from two to one.

Better information on the nature of low production well sites is needed to assess an appropriate model well facility if a model facility is even appropriate given the diversity of production across basins.

d. Use of 1995 emissions factors raises issues of accuracy.

The EPA's use of 1995 emissions factors to develop its Model Low Production Well emissions estimates must be tested for accuracy. The 1995 effort for oil and natural gas production facilities is primarily based on an American Petroleum Institute ("API") document – API 4615 – that was prepared for generally predicting emissions levels. This is a different purpose than creating emissions factors for the purpose of regulations.

Among the key issues that bear here is whether that 1995 analysis attempted to determine distinctions between large production facilities and low production facilities. In the instant case, that distinction is significantly important because the EPA is using these factors for exactly the purpose of regulating low production wells and determining the effectiveness of its proposed program.

To present the issue in the context of its uncertainty, the emissions factor for valves – the largest component of emissions in the EPA's natural gas Model Low Production Well – is 4.5E-03 or 0.0045 kg/hr/component. The API analyzed the effectiveness of LDAR programs and compared them to EPA's assumptions in designing its LDAR program. It found that the EPA's assumptions regarding initial failure rates and the time before further maintenance or repair of equipment was necessary were inaccurate. The API data demonstrated that the EPA's assumptions overstated initial failure rates and predicted the need for further maintenance too soon. Consequently, the combination of these assumption overstates the benefits of the EPA LDAR and its cost-effectiveness. Additionally, the API's letter to the EPA submitting its information on February 22, 2018, includes updated emissions factors for component leaks at oil and natural gas production facilities. In the case of valves, the new emissions factor is 1.1E-03 or 0.0011 kg/hr/component. This factor that is 25 percent of the factor used by EPA in its Model Low Production Well.

The point here is that there are key assumptions that are highly questionable and more accurate information is essential.

3. The EPA's Model Low Production Well needs improvement.

The EPA creates a Model Low Production Well to define and determine the emissions and the effectiveness of its proposed low production well fugitive emissions program. The Independent Producers continue to evaluate and have certain concerns with the approach that the EPA takes in developing low production well emissions. The EPA appears to be fixated on the use of component counts to define emissions. While it is reasonable to associate the number of connections and the potential for leaks, we continue to believe that emissions from low production wells are inherently different from large production wells because of the basic physics of production and how operators change the physical equipment as production warrants.

When oil and natural gas wells are initially produced, the geologic forces that are released through the well bore drive initially higher production rates. Like releasing air from an inflated balloon, high pressure from the formation pushes flow of oil and natural gas through the well. These higher pressures and strong volumes of fluids define the design parameters for the well and the surface support equipment when the well is first drilled.

However, as wells age and production declines, conditions change. Pump jacks, if not used from the onset of production, are required to pull oil from the formation; compressors may be needed to suck natural gas from wells, while other equipment is removed or downsized. Secondary and tertiary recovery methods are used to produce more oil and natural gas from conventional formations.

These changes have consequences on the nature of emissions, particularly fugitive emissions. Like the challenge of getting the last air out of a balloon, the movement of gas molecules will follow the path of least resistance. Movement from the process equipment to the atmosphere is harder than moving to the production vessel where the flow is designed to go.

For these reasons, the Independent Producers object to relying upon component counts as the primary if not sole basis for estimating low production well emissions. Nevertheless, if the EPA intends to use component counts, we must assure that its assumptions are accurate. Based on a review of the TSD associated with the Reconsideration Rulemaking and data collection from many individual companies from various plays across the country, the Independent Producers believe the EPA continues to overestimate emissions from low producing wells.

a. The model plant is dominated by two elements – valves and storage vessels.

Because the EPA relies on component counts for its emissions estimates, it is essential to look at the mix of components and the application of emissions factors to them. The EPA divides its model facility by different types of equipment – wellheads, separators, headers, heater treaters, glycol dehydrators and storage vessels. For each type of equipment, it counts the following components – the number of specific equipment types on site, valves, connectors, open ended lines ("OELs") and pressure relief valves ("PRVs"). In reviewing the TSD, the dominant components driving the model facility plane are the number of valves and the number of storage vessels per facility. Following are the tables from the TSD for the Model Low Production Well.

Table 2-2. Average Fugitive Emissions Component Count for Low Production Well Site Model Plants

Production Equipment	Model Plant Equipment Counts	Average Component Count Per Unit of Model Plant ^a				
		Valves	Connectors	OELs	PRVs	Thief Hatches
Low Production Natural Gas Well Site Model Plant

a. Data Source for average component count per equipment type: EPA/GRI, CH₄ Emissions from the Natural Gas Industry, Volume 8: Equipment Leaks, Table 4-4 and 4-7, June 1996. (EPA-600/R-96-080h). Values were multiplied by the rounded equipment count for model plant component counts.

In the most notable example above, the EPA's use of the 25 gas production facilities, with its high count for valves, drives an emission estimate that the EPA then uses to justify its

formulation of a low production well fugitive emissions program. These estimates are shown below:

Model Plant Component Type	Model Plant Component Count	Uncontrolled Emissions Factor* (kg/hr/component)	Uncontrolled Emissions (tpy)	
			Methane ^b	VOC ^c
Low Production Gas Well Site				
Valves	100	4.5E-03	3.01	0.84
Flanges	0	3.9E-04	0.00	0.0
Connectors	349	2.0E-04	0.47	0.13

Total			4.80	1.34

Low Production Oil Well Site				
Valves	23	4.5E-03	0.69	0.19
Flanges	41	3.9E-04	0.11	0.03
Connectors	32	2.0E-04	0.04	0.01
OEL	0	2.0E-03	0.00	0.00
PRV	2	8.8E-03	0.12	0.03
Thief Hatch	1	0.1296	0.87	0.24
Total			1.83	0.51

Low Production Oil Well Site w/Associated Gas				
Valves	44	4.5E-03	1.33	0.37
Control Valves	41	3.9E-04	0.11	0.03
Connectors	105	2.0E-04	0.14	0.04
OEL	1	2.0E-03	0.01	0.00
PRV	3	8.8E-03	0.18	0.05
Thief Hatch	1	0.1296	0.87	0.24
Total			2.63	0.73

In each of these cases, the primary factors in the emissions profile are valves and thief hatches on storage vessels. If either of these factors is overstated, the impact on the cost effectiveness of the fugitive emissions regulations can be significant. As we presented above, the emissions factor for valves comes from general information on oil and natural gas production operations in the mid-1990s. Among the questions it raises are:

- Is the emission factor accurate for low production wells?
- Would the emission factor be the same for oil service and gas service?

- Do emissions vary with valve activity?

The second key component in the calculation involves an accurate assessment of the number of valves at a low production well facility. There are many factors that define the number of valves at a particular facility, obviously one being the amount of equipment at the site. Equipment changes over time as facilities respond to declining production. Different parts of the country need different equipment. For these reasons, the EPA's use of a limited number of wells – 25 to 27 wells in the Barnett Shale for natural gas production raises clear questions about whether this limited selection of wells is reflective of low production wells nationally. It creates an even more significant question in the context of a possible nationwide existing source regulatory initiative under Section 111(d) which would bring in 770,000 wells with life spans covering decades of production.

For this reason, we solicited information from oil and natural gas producers from across the nation regarding the structure of their low production facilities. This effort presents in clearer focus that attempting to use a model well facility to justify regulations falls short of the regulatory burden that EPA should bear in understanding the consequences of its actions.

b. Industry information from across the country shows different equipment counts that dispute the model well which is primarily based on the Fort Worth Study.

In response to these Comments, the Independent Producers solicited available information on component counts from low production wells across the nation. These results are not intended to be presented as statistically accurate or fully representative of the population of low production wells. However, they are illustrative of the challenge of defining a Model Low Production Well plant. We obtained information from operations in thirteen states – Arkansas, Colorado, Indiana, Kansas, Kentucky, Michigan, Montana, Nebraska, Ohio, Oklahoma, Pennsylvania, Texas, and Virginia. Information was provided on over 2,400 wells, almost 1,700 of which are natural gas wells. We defined natural gas wells as well with a gas/oil ratio of 5.0 based on BOE. Because the most questionable aspect of the EPA model well calculations relates to the assumptions related to the number of valves in natural gas operations, we will present that information here.

i. Number of valves is well below model plant; wellhead assumption is too high.

Following are tables from the states with reported information from natural gas sites. A first point in this information that bears on the calculations is that this natural gas low production well information shows that typical plant has one wellhead rather than the two wellheads in the EPA model plant. Inherently, this likely reduces the number of valves, but it should not be interpreted to mean that doubling the number of valves would be appropriate in the creation of a model plant with two wellheads. Moreover, it also emphasizes the burden of the Optical Gas Imaging ("OGI")-based fugitive emissions program on these smaller operations. These tables provide information on the average number of storage vessels, wellheads and valves at these natural gas production plants.

PENNSYLVANIA

The following table presents information based on 1631 natural gas well sites.

State	Number of Storage Vessels	Number of Wellheads	Number of Valves
PA	1	1	23

OKLAHOMA

The following table presents information based on 27 natural gas well sites. However, two of these sites have larger numbers of valves; 236 and 177. If those sites were removed from the total, the average number of valves would drop to 24 per wellsite.

State	Number of Storage Vessels	Number of Wellheads	Number of Valves
OK	2	1	38

OHIO

The following table presents information on 10 natural gas well sites.

State	Number of Storage Vessels	Number of Wellheads	Number of Valves
OH	10	10	22

TEXAS

The following table presents information on 10 natural gas well sites.

State	Number of Storage Vessels	Number of Wellheads	Number of Valves
TX	2	1	25

KANSAS

The following table presents information on six natural gas well sites.

State	Number of Storage Vessels	Number of Wellheads	Number of Valves
KS	1	1	11

MICHIGAN

The following table presents information on four natural gas well sites. However, one of these sites has 161 valves and 5 storage vessels. If this site was removed, the average number of valves would decrease to 17.

State	Number of Storage Vessels	Number of Wellheads	Number of Valves
MI	3	2	53

KENTUCKY

The following table presents information on two natural gas well sites.

State	Number of Storage Vessels	Number of Wellheads	Number of Valves
KY	1	1	14

VIRGINIA

The following table presents information on one natural gas wellsite.

State	Number of Storage Vessels	Number of Wellheads	Number of Valves
VA	1	1	12

- c. EPA model plant calculations attribute 80 percent of low production natural gas wells to valves (63 percent) and thief hatches (18 percent) and 85 percent of low production oil wells to valves (38 percent) and thief hatches (48 percent). These calculations are based on questionable emissions factors.*

Deconstructing the EPA's Model Low Production Well reveals that the primary factors in defining emissions are valves and thief hatches. This holds true for both natural gas and oil wells although valves are far more of a factor in the Model Low Production Well. The Independent Producers believe this calculation is highly questionable. As the Independent Producers have set forth above, both of the underlying assumptions on valves – the emissions factor and the number of valves – are not appropriately validated for the purpose of creating a costly regulatory program.

The valve emissions factor hinges on assumptions of the initial levels of emissions prior to the LDAR program and the recurrence of those emissions levels. Yet, the API analysis submitted to the EPA in February 2018 provides demonstrable data to produce an emissions factor approximately 25 percent of the factor the EPA used in its estimate.

Regarding the number of valves, the EPA's determination in its model facility that a low production wellsite includes 100 valves does not reflect all areas in the country that would be affected by these regulations, particularly as existing sources are affected in future regulatory actions.

i. If these assumptions are incorrect, it significantly changes the cost-effectiveness assumptions of the EPA fugitive emissions program.

Without addressing all of the assumptions in the EPA Model Low Production Well plant that are called into question by the additional information in the material that the Independent Producers acquired from the 13 states where we were able to get limited information, the information above on valves and the questionable emissions factor alone change the nature of the EPA's cost-effectiveness analysis.

For example, if the number of valves used for the natural gas Model Low Production Well plant is changed to 20 and the API emissions factor for valves is used to calculate the fugitive emissions program's cost-effectiveness using the EPA spreadsheet provided in the Docket¹², cost per ton of recovered methane increases by a factor of about 2.5. More tellingly, the amount of recovered methane would be estimated at 0.092 mcf. It is hard to imagine that this miniscule amount of methane would even be detectable; it is unlikely to even be measurable as additional product.

Moreover, these calculations do not address the cost of the EPA proposed program. As we have shown earlier, past history with OGI programs has demonstrated these programs to have been far costlier than the EPA presumed. To put an additional point on it, for the Pennsylvania wells that were identified in this inventory, the operator estimates that the cost of the biennial EPA OGI fugitive emissions program would exceed \$800,000 – or \$400,000 per year. The average production of those wells is about 6 mcf.

d. Assessing the cost impact on low production wells needs to look beyond the common tests of cost effectiveness in a cost per ton of reduced emissions to address the cost impact in the profitability of these small wells.

In the context of low production wells, the EPA's analysis of the cost effectiveness of its regulations, as flawed as it may be, also fails – like most cost-effectiveness analyses to address a more critical issue. Cost-effectiveness analyses typically look at the cost per unit of pollutant recovered. For low production wells, wells generally operated by small businesses, there is a remaining significant issue – whether the absolute cost can be absorbed by the operations that are regularly economically challenged.

Not surprisingly, the impact of a fugitive emissions program is significantly different between small and large wells. For the past several years, the EDF has polluted the air with an analysis that it developed showing that a variety of methane controls are cost effective when that is not the case. The EDF states these controls only cost a few cents.

¹² Proposed_Rule_OOOOa_TSD_Section_2_-_OGI_Compressor_Model_Plant_Costs

The problem is that the EDF's analysis is flawed and, when the average low producing well produces 22 mcf per day, a few cents per mcf is highly significant. Moreover, the economic assumptions can be as significant as the emissions assumptions. In the Reconsideration Rulemaking, the EPA indicates that it uses a natural gas value of \$3.42/mcf. This amount may reflect current natural gas prices at a time where storage limitations and high demand have driven prices higher. However, it fails to reflect that prices in the past several years have been well below this level. In fact, in the past two years, national natural gas prices have triggered the Marginal Well Tax Credit with the Internal Revenue Service calculating that the average price in 2016 was \$2.38/mcf and in 2017 was \$2.17/mcf. Moreover, producers do not receive the full value of the sales price; they must pay royalties and taxes that reduce the amount received by about 25 percent. Using the IRS average value for those two years (\$2.22/mcf), the producer would then receive about \$1.67/mcf for any recovered gas.

The EPA's Model Low Production Well analysis calculates that about 280 mcf/yr are emitted and 30 percent is recovered by its LDAR program – 84 mcf/yr. We believe this determination is too high, that API's emission factor is more accurate. Using the high valve count that the EPA assumes for its model well and the API emissions factor yields a recovery amount of 44 mcf/yr. It should be noted that this amount is about 0.12 mcf/d and one has to raise a question of whether this amount can even be found or will show up in the daily production measurements.

Using the more realistic product prices, this presumed recovery adds about \$73.50 to the annual income of the Model Low Production Well or about \$36.75 to the income of a well. It is noteworthy to point out that even this small recovery may overstate the amount since it is highly dependent on the number of valves at a facility.

The larger question is what impact does this have on a low producing well. Using the cost information above, the average low producing well (22 mcf/d) would receive daily income of \$36.75 (\$13,400 per year).

It is difficult to determine operating costs but the EIA released a report in March 2016, *Trends in U.S. Oil and Natural Gas Upstream Costs*, which assessed a wide range of costs and looked at several production areas. One of its evaluations addressed operating costs in the Marcellus play – the world-scale natural gas play in the northeastern states. The report estimated that Marcellus operating costs range from \$12.36/BOE to \$29.60/BOE. Using the standard 1 BOE = 6 mcf conversion, it produces operating costs ranging from \$2.06/mcf to \$4.93/mcf. Applying these costs to the average low producing well results in a daily cost range of \$45.32 to \$108.46.

Consequently, the average low producing well would have to have a natural gas price in the range of \$2.06/mcf to \$4.93/mcf to break even. In Pennsylvania, where the average low production natural gas well produces closer to 6.0 mcf/d and the typical wellsite is one well rather than two, the challenge is even greater. Income would be about \$10.00/day with operating costs in the range of \$12.00 to \$29.00 daily. In this difficult financial situation, the application of the EPA LDAR program is a far more significant factor than the EPA has presumed in its analysis, given that the amount is essentially unmeasurable.

Clearly, there are many factors that come into play in this analysis – price of natural gas, cost of the LDAR program, operating costs. The fundamental point is that an LDAR program that *may* be justified for large producing wells will have a very different impact on small ones. The EPA should develop a methodology that reflects these differences and it has not.

4. The DOE has announced a research program to determine more accurate assessments of low production well emissions.

On October 23, 2018, the DOE, Office of Fossil Energy ("FE"), announced a research program to address low production (marginal) well methane emissions. The announcement stated:

The U.S. Department of Energy's (DOE) Office of Fossil Energy (FE) has approved an unsolicited proposal, titled *Quantification of Methane Emissions from Marginal (Small Producing) Oil and Gas Wells*, received from GSI Environmental Inc. (GSI). The data collected from well sites in basins across the United States will help address critical knowledge gaps and support best management practices that are appropriate for marginal wells.

This effort complements related DOE research and analysis projects conducted by the National Energy Technology Laboratory (NETL) to improve understanding of methane emissions and identify potential reduction strategies that can improve the operational efficiency of the Nation's natural gas production and delivery systems.

In June 2016, the U.S. Environmental Protection Agency (EPA) published a final rule in the Code of Federal Regulations to amend the New Source Performance Standards at subpart OOOO, and finalize new standards at subpart OOOOa to reduce methane emissions from new and modified oil and gas facilities. The updated standards included requirements for marginal well sources—oil wells that produce less than 15 barrels per day or gas wells that produce less than 90,000 cubic feet per day—which were not previously addressed.

EPA's decision was based on limited data. The Agency had presumed emissions from marginal and non-marginal well sites were comparable, but that conclusion was derived from data amassed from studies employing a wide variety of technical approaches, none of which were designed to assess emissions specifically from representative populations of marginal well sites.

As part of an ongoing regulatory review and reconsideration process, on September 11, 2018, EPA issued proposed targeted improvements to the 2016 standards that aim to streamline implementation, reduce duplicative EPA and state requirements, and decrease unnecessary burdens on domestic energy producers. The Agency continues to review other aspects of the 2016 rule that could be the subject of future rulemaking.

While the costs of regulatory compliance impact all producers, small independent oil and gas producers who operate many of the over 700,000 marginal wells that dot the United States could be disproportionately impacted, with associated economic impacts to energy production, states, and communities.

Recognizing these challenges, GSI proposed to collect and evaluate representative, defensible, and repeatable data from each type of well (marginal vs. non-marginal, oil vs. natural gas). This data, together with data from existing sources, will be compiled, evaluated for usability and representativeness, and analyzed to answer two key questions:

- What conclusions can be reliably drawn regarding the relative methane emissions among significant marginal and non-marginal well site populations based on existing available information?
- What are the key gaps in understanding the relative frequency and magnitude of emissions from marginal vs. non-marginal well sites?

Once these questions are addressed, GSI will develop a focused and detailed scope of subsequent field investigations, as appropriate, to address critical data gaps. Study conclusions will also focus on identification and implementation of appropriate best management practices, so that the United States can continue to rely on traditional oil and natural gas resources for clean, secure, and affordable energy while enhancing environmental protection.¹³

This DOE study provides the EPA the opportunity to do what it should have done as it initially developed Subpart OOOOa – collect direct emissions data on low production wells. This data would allow the EPA a baseline that shows the distinctions between large wells and low production wells and the differences that may exist between types of wells and between production regions.

The EPA should embrace this DOE action.

5. The EPA should make the following changes to the low production well regulations.

First, the EPA should retain a low production well distinction in the regulations. Regulations designed for large high production wells do not function appropriately for low production wells averaging 2.6 B/D of oil or 22 mcf/d of natural gas.

Second, the EPA should restructure the regulation to provide that as wells decline to the low production well threshold, these wells would move into the low production well requirements.

Third, the EPA should use the U.S. Tax Code definition of stripper wells as the low production well definition. Both the Tax Code definition and the proposed Subpart OOOOa definition use the same 15 B/D BOE basis. However, the Tax Code interpretation is well understood by both producers and federal regulators. Its use would prevent litigation over interpretation of the new Subpart OOOOa language. The EPA can address enforcement and compliance concerns by establishing an initial production threshold that would trigger a one-year

¹³ <https://www.netl.doe.gov/node/5775>

period to determine whether a well is a low production well or not. The current proposal using production after 30 days does not reflect the realities of natural production declines.

Fourth, the EPA should await the results of the recently announced Department of Energy *Quantification of Methane Emissions from Marginal (Small Producing) Oil and Gas Wells* project to develop low production well regulations, if any are cost-effective or appropriate given the low emissions from low production wells. The EPA's current use of available data that was never taken with the intent of being used for low production well regulation is inappropriate. The database is too small and, more importantly, too anecdotal to be used for nationwide regulations of the diverse population of low production wells. The EPA should follow the path that it took with regard to a fugitive emissions program in the October 2016 CTG for existing oil and natural gas production facilities in ozone nonattainment areas. In that action, the EPA deferred the institution of a fugitive emissions program until an undefined future date. Given that the results of the DOE project are essential to developing sound regulations, if any are justified, this approach would be consistent with the CTG decision.

6. The EPA should exempt booster compressors associated with low production wells.

A forgotten but very susceptible piece of equipment often necessary for gas production from low producing wells with low pressure reservoirs is the booster compressor. There are many situations in the Appalachian Basin as well as other basins, where a booster compressor managed by small operators is necessary to move natural gas from a low pressure well or wells into higher pressure gas flow lines. Often located at or near a wellhead, these booster compressors operate with suction pressures near if not below atmospheric pressure and discharge pressures no higher than 100 psi. The Subpart OOOOa requirement for quarterly fugitive emission surveys with very expensive optical gas imaging equipment can make the use of a booster compressor uneconomical, and leave large portions of a small gas well's otherwise producible reserves in the ground. A picture of a typical booster compressor is below:

The potential to emit fugitive emissions from a booster compressor is very small. At the pressures they operate, the suction side, operating near atmospheric pressure, has little potential to leaks and the discharge side usually has no more than a fitting connecting the compressor to the flowline. Again, booster compressors have very few connections that could leak. Reciprocating compressors, even those used as booster compressors, regulated under Subpart OOOO, are already required to have the rod packing replaced every five years.

Booster compressors should be treated as wellhead equipment for low producing gas wells sufficing to have periodic audio, visual, and olfactory ("AVO") surveys that can be done by small operators, and eliminate the burdensome and expensive optical imaging surveys and recordkeeping that is typically already done at large compressor stations.

III. SUBPART OOOOa STORAGE TANK COMMENTS

A. Background/Proposal

In the reconsideration amendments, the EPA has proposed to change how operators calculate potential emissions and applicability of the storage vessel requirements under the rule. The EPA also proposes to impose additional recordkeeping and reporting requirements related to the applicability determination for both affected and non-affected storage vessels. Specifically, the EPA proposes to:

- Limit the circumstances and operational configurations operators may use to average potential emissions across a tank battery for purposes of determining applicability of a particular storage vessel.
- Revise the definition of "maximum average daily throughput" to require that operators use only the days that production is actually sent to a particular storage vessel during the 30-day evaluation period to calculate maximum average daily throughput for the storage vessel.
- Impose additional limits and criteria on what constitutes a "legally and practically enforceable limit" for purposes of determining storage vessel potential to emit ("PTE").
- Require additional recordkeeping for both affected and non-affected facilities related to storage-vessel applicability determinations.

The EPA's proposed reconsideration amendments present a number of technical and practical concerns. While the EPA claims that some of these changes are mere "clarifications," The Independent Producers have significant concerns because the EPA's proposals represent a departure from the prior EPA statements and practice and raise concerns related to retroactive application and enforcement. Accordingly, the Independent Producers provide these specific comments and suggestions on each of the above-described topics.

B. Maximum Average Daily Throughput and Averaging Emissions Across Tank Batteries.

In the proposed reconsideration amendments, the EPA expresses concern that operators have been "incorrectly averaging emissions across storage tanks in tank batteries when determining the potential for VOC emissions."¹⁴ The EPA states that "[d]ividing an entire battery's throughput by the number of storage vessels in the battery would greatly underestimate flash emissions from the first storage vessel connected in series, which is where liquid pressure drops from separator pressure to atmospheric pressure."¹⁵ To attempt to extend regulatory controls over these tank batteries, the EPA proposes to "clarify" how PTE is calculated for different storage-tank configurations and operations. This includes defining when it is appropriate to divide a tank battery's throughput across an entire tank battery to determine PTE for individual storage tanks for Subpart OOOOa applicability purposes. For example, the EPA states that averaging "could be appropriate" where a tank system is configured in parallel with a "splitter system" and all liquids "initially flow in equal amounts" to individual tanks, but it would not be appropriate when tanks are configured and operated with liquid product flowing in series. As a consequence, the EPA proposes including a revised definition of "maximum average daily throughput" that would specify the exact method of calculation required to determine "daily throughput for an *individual* storage vessel over the days that production is routed to that storage vessel during the 30-day evaluation period." Despite the language in the preamble to the proposal, the EPA's proposed definition appears to prohibit averaging of tank emissions in all

¹⁴ 83 Fed. Reg. at 52,084.

¹⁵ *Id.* at 52,085.

situations, including those under which the EPA suggests averaging may be appropriate (*e.g.*, tanks configured in parallel).

The Independent Producers disagree with the EPA's contention that under Subpart OOOOa (or its predecessor, Subpart OOOO) operators have been "incorrectly" averaging emissions across tank batteries. Subpart OOOOa currently provides that storage tank PTE "must be calculated using a generally accepted model or calculation methodology."¹⁶ Averaging has historically been and continues to be an acceptable methodology for estimating emissions from storage tanks – particularly from tanks that are part of a controlled tank battery. The Independent Producers also disagree with the technical premise relied upon by the EPA to support its assertion that averaging is categorically inappropriate for certain tank configurations. And finally, the Independent Producers have concerns with the EPA's proposed definition of "maximum average daily throughput" as it appears to categorically prohibit averaging storage tank emissions across a tank battery and also overestimates potential emissions by relying only on the days during which throughput is actually sent to a specific storage vessel. Each of these changes directly conflict with Executive Order 13783, issued by President Trump, which directs the heads of all federal agencies to "review all existing regulations, orders, guidance documents, policies, and any other similar agency actions . . . that potentially burden the development or use of domestically produced energy resources, with particular attention to oil, natural gas, coal, and nuclear energy resources."¹⁷ Here, the EPA proposes revisions that would significantly increase the burden on domestic producers of oil and gas.

1. The EPA's proposal to prohibit averaging of throughput across tank batteries inappropriately ignores fundamental operational processes.

The EPA's expressed concerns about averaging ignore that many new and modified tank batteries not subject to Subpart OOOOa are either: (1) already controlled pursuant to a state requirement; or (2) if uncontrolled, have a system that allows for the build-up of pressure across the head space of the entire tank battery and collection system. *See Appendix A* for examples of diagrams/drawings of sample facilities manifolded together. Though the Independent Producers believe that there is a technical basis for the EPA to allow averaging in both of these scenarios, the Independent Producers understand the EPA's concern that averaging across multiple tanks in a battery may allow certain storage tank emissions to remain uncontrolled. As a result, the Independent Producers proposed that, in order to alleviate the EPA's concern regarding uncontrolled storage tanks, while still acknowledging the technical reality of how tanks' vapors equalize across a tank battery, the EPA allow averaging (regardless of tank configuration) for all storage vessels that share a common vapor space within a controlled tank battery. The Independent Producers believe that such averaging methodologies should be allowed both for initial applicability determinations and for determinations as to whether tank vessels meet the thresholds below which the storage tank requirements in Subpart OOOOa (or Subpart OOOO) apply.

¹⁶ 40 C.F.R. § 60.5365a(e); *id.* § 60.5430a ("Maximum average daily throughput means the earliest calculation of daily average throughput during the 30-day PTE evaluation period employing generally accepted methods.").

¹⁷ 82 Fed. Reg. 16,093 (Mar. 28, 2017).

The Independent Producers wish to put a fine point on why the EPA's proposal is not technically valid, why averaging has a sound basis in engineering, and importantly, why averaging actually addresses the EPA's concern about flash emissions. Tank batteries, controlled by a common flare or combustor system or vented through one common pressure relief valve ("PRV") typically share vapor space (the tank volume above the liquid) and joint piping used to collect generated vapors and convey them to the control device. Because the vapor collection piping is typically free of restrictions, vapors flow both into and out of each tank within the battery and into overflow piping on a continuous basis, and vapors will always flow from high pressure areas to low pressure areas when flow is mechanically unrestricted. In this configuration, the flash emissions from the first tank will not be immediately emitted, but will flow into the other tanks and vent line space associated with the battery as a whole until the total pressure in the system exceeds the back-pressure of the flares, control device, or in systems without controls, the pressure relief valve. Only then will the emissions be released from either the pressure relief valve or combusted by the control equipment.

Given that gas is allowed to equalize among the tank vessels in a manifolded system, there is no technical basis for the EPA's concern about emissions from the first storage vessel in the series being underestimated. The EPA inappropriately assumes that emissions in a manifolded system are individually emitted from each tank and that they result only from the oil being produced into that given tank. In reality, for the reasons described above, the vapors being emitted from the tank battery at any point in time may have originated from any tank in the battery.

Based upon the EPA's technical approach in these proposed reconsideration amendments it may be that the EPA misunderstands how these systems typically work. For example, in the preamble to the proposed Subpart OOOO, the EPA stated: "[d]uring times of flash emissions, tanks are designed such that the flash emissions are released through a vent on the fixed roof of the tank when pressure reaches just a few ounces to prevent pressure buildup and resulting tank damage."¹⁸ However, for facilities under the configuration described above, this individual emitting from tank thief hatches does not occur in the manner described by the EPA. Rather, vapor pressure equalizes across the system and emissions are released only when the pressure in the battery as a whole exceeds the backpressure of the PRV or the emissions proceed through the combustion device: whether emissions will or will not occur is dependent on the capacity of the entire vapor control system, not the individual storage tank. Thus, contrary to the EPA's suggestion in the proposed reconsideration amendments, dividing an entire tank battery's throughput by the number of storage vessels in the battery would be an appropriate and acceptable methodology in cases where all vessels in the tank battery share vapor space, emissions generated in one vessel equalize into the other vessels in the tank battery, and emissions are eventually controlled by the same control device or released through common PRVs. In this context, it is irrelevant whether the tanks are operated in series or in parallel, because it is not the throughput of the liquids through any single vessel within the system that determines potential emissions, but a number of other factors, including the operation of the combined vapor control system for the integrated tank battery. Accordingly, the determinant

¹⁸ 76 Fed. Reg. 52,738, 52,764 (Aug. 23, 2011).

factor for allowed averaging across multiple storage vessels within a system is shared vapor space, rather than the EPA's proposed focus of liquid filling configuration.

2. The EPA's proposal to eliminate averaging is inconsistent with recent consent decrees related to the design and operation of vapor control systems on storage tanks.

The Independent Producers' technical explanation above, on how emissions are released from storage tank batteries, comports with the EPA's interpretation in recent enforcement cases. In the past several years, the EPA has entered into a number of consent decrees related to the design, and operation and maintenance of vapor control systems on storage tanks. In each of those consent decrees, the EPA acknowledges (and in fact demands) that the operator consider the vapor control system as a whole in determining how to design to avoid emissions from storage tanks. Specifically, the consent decrees typically define a vapor control system in the following manner: the system used to contain, convey, and control vapors from one or more storage tank(s) (including flashing, working, breathing, and standing losses), as well as any natural gas carry-through to storage tanks. A vapor control system includes a tank system, piping to convey vapors from a tank system to a combustion device and/or vapor recovery unit, fittings, connectors, liquid knockout vessels or vapor control piping, openings on storage tanks (such as thief hatches and any other pressure relief devices, and emission control devices). Through this definition, the EPA makes clear that it treats the vapor control system as one system, specifically a system that includes all storage vessels sharing a common vapor manifold. The EPA's proposal that prevents averaging across individual tanks even for controlled tanks and instead requires a theoretical assessment of emissions from individual tanks, even where they share a common vapor space, is entirely inconsistent with the underlying theory of the EPA's consent decrees and their treatment of vapor control systems – particularly for facilities with existing control requirements under state or permit requirements.

C. The EPA's Concern About the Amount of Storage Vessels Subject to Subpart OOOOa is Overstated and Unfounded.

As support for its position that operators have been "incorrectly averaging emissions across storage tanks," the EPA states that inspection data and compliance reports for the 2016 Subpart OOOOa indicate that operators reported "fewer than expected number of reported storage vessel affected facilities."¹⁹ But the number of storage vessels subject to Subpart OOOOa is not in fact surprising and presents no basis for concern.

In the preamble to the proposed Subpart OOOO, the EPA clearly expressed that it originally developed the storage tank requirements because it "believe[s] it is important to control tanks with significant VOC emissions under the proposed NSPS."²⁰ The EPA's recently expressed concerns about the number of tanks reported under Subpart OOOOa seem to be focused on an attempted regulatory expansion with no corresponding environmental benefit. The interpretation ignores that a significant number of states already have storage tank control requirements that are similar to or even more rigorous than those presented by Subpart OOOO or

¹⁹ 83 Fed. Reg. at 52,084.

²⁰ 76 Fed. Reg. at 52,763.

OOOOa. Those many programs require control of storage tanks and therefore provide operators with an enforceable limit on the VOC emissions from those storage tanks. As a result, it should be expected that facilities complying with a state control requirement would not also be subject to potentially duplicative, or even inconsistent, requirements under Subparts OOOO or OOOOa. In fact, the EPA has previously acknowledged that the focus and intent of the Subpart OOOO and OOOOa storage tank provisions was to ensure that storage tanks *not otherwise subject to state control requirements* are subject to a corresponding federal requirement to control VOC emissions.²¹ The EPA's statement now, that operators reported fewer than expected storage vessels, simply means that the EPA's estimates were not entirely accurate at the forefront; a fact that is far from surprising given the complex nature of the issue.²² In fact, even if operators followed the EPA's proposed methodology for calculating emissions from individual storage vessels, the EPA may not see as marked an increase in storage vessels subject to NSPS OOOOa as it thinks. As noted elsewhere, following the EPA's methodology for calculating emissions from individual storage tanks would potentially result in many instances where the first storage vessel in a battery is subject to Subpart OOOOa but none of the remaining storage vessels are subject. Thus, the actual number of tanks reported under Subpart OOOOa might not increase to the extent the EPA expects.

Finally, and as noted above, because these storage tank systems are controlled and function as one vapor control system, there is no basis to require companies to consider individual emissions from individual tanks as such a scenario is inconsistent with the way these facilities are operated.²³ Thus, the EPA's comment that companies have been incorrectly averaging is inaccurate and misleading. As the EPA notes in the Reconsideration Rulemaking, "[o]perators should ensure that the determination of the potential for VOC emissions reflects each storage vessel's actual configuration and operational characteristics."²⁴ However, the EPA fails to do exactly that when it ignores that many of these vessels share a common vapor space and either have a pressure relief valve or control device that equalizes pressure across the entire

²¹ See EPA Letter to Matthew Todd, 5 (Sept. 28, 2013) (acknowledging that the EPA's original estimates for the number of affected facilities under Subpart OOOO excluded facilities already subject to state emission-control requirements for storage tanks); 78 Fed. Reg. 22,126, 22,130 (Apr. 12, 2013) (subtracting from estimated number of affected facilities storage tanks in the eleven states with existing control requirements).

²² See, e.g., 78 Fed. Reg. at 22,130 (revising original Subpart OOOO estimates for storage tanks from 304 tanks per year to approximately 11,000 per year).

²³ Importantly, for controlled tank batteries, improvements to storage tank design, operation and maintenance have been adopted by operators as new information about those facilities has been identified, including through the EPA's September 2015 Compliance Alert. Though these issues are not relevant to the applicability of the storage tank requirements in Subpart OOOOa to storage vessels, these improvements render some of the EPA's historic concerns less realistic as they help ensure that emissions remain in the vapor collection system until combusted by emissions control equipment. Significant work has also been done on the functionality and operation of thief hatch and PRVs, and new thief hatch and PRV designs allow for even greater set pressures, thus accommodating higher tank vapor pressures and reducing fugitive emissions when compared to similar equipment just a few years old. The net result is an overall improvement in storage vessel vapor collection and control system operation that keeps more vapors in the system with more efficient control of the entire tank battery – especially during maximum throughput conditions – and that demonstrates a concerted effort by industry to address the concerns and issues with storage tank emissions first raised by the EPA in its September 2015 Compliance Alert.

²⁴ 83 Fed. Reg. at 52,085.

battery. The EPA's failure to acknowledge these key operational characteristics is particularly egregious for tanks that are already controlled.

D. The EPA's Proposal to Calculate Individual Tank Emissions Based Upon Throughput to Each Individual Tank is Technically Flawed and Overly Burdensome.

Instead of averaging throughput and emissions across a tank battery, the EPA now contends that operators should be determining throughput for each individual storage vessel. The EPA proposes two separate methods for accomplishing this feat: (1) actively measure daily throughput to each individual tank via auto-gauging or manual gauging,²⁵ or (2) determine for each loadout period, the highest average daily throughput for each storage vessel.²⁶ For the second method, where tank throughput is not monitored daily, the EPA suggests the following procedure for determining individual tank throughput: (1) measure the liquid height in the storage vessel at the start and completion of loadout of liquids from the storage vessel; and (2) divide the volumetric throughput calculated from the change in liquid height over the number of days in the production period.²⁷ The EPA defines a "production period" as the date "production begins to be routed to a storage vessel" until the date "throughput is routed away from that storage vessel or when a loadout occurs from that storage vessel."²⁸ If a tank system undergoes multiple loadouts during the thirty-day evaluation period, operators must use the maximum of the production period average daily throughput values to calculate the potential emissions from the individual storage vessel.²⁹

The EPA's proposal is overly burdensome, contradicts "generally accepted" methods to calculate emissions, and ignores the technical complexity and feasibility of such an assessment. First, the EPA assumes that many operators have a readily available mechanism for determining the production within each tank on a daily basis. Equipment for determining the throughput of individual tanks is not available in all or even most instances and does not reflect a generally accepted method for evaluating production to or emissions from individual storage vessels. Whether a mechanism for determining daily production from each tank exists depends upon a number of factors, including operational configuration and commercial considerations. In most instances, there is no need to assess the production in any individual tank as liquids are not removed until the capacity of the tank battery as a whole reaches certain levels. This is particularly true at facilities that utilize lease automated control technology ("LACT") systems that automatically release liquids into a gathering pipeline upon reaching certain thresholds in the storage vessel connected to the LACT unit. Even at facilities that are loaded out by truck, there is no operational basis for allocating production from the entire battery to individual tanks.

²⁵ As to this first method, the Independent Producers also want to clarify that the EPA's proposed language in the preamble that refers only to "automated gauging" generally, should be more specifically limited to scenarios where operators employ *daily* gauging (whether manual or automated). The Independent Producers stress, however, that regardless of the type of gauging employed, this should not be required on a per-tank basis.

²⁶ See 83 Fed. Reg. at 52,084.

²⁷ *Id.*

²⁸ *Id.*

²⁹ *Id.*

Requiring operators to undertake such granular and nuanced information for tank batteries with existing controls already in operation provides no environmental benefit and does not comport with generally accepted methods for operating these systems.

Finally, the EPA appears to assume that the emission factor will be the same for all of the production in a storage tank battery – regardless of whether the production is contained in the first tank in a series or the last. Such an assumption is inconsistent with the EPA's own statements in the preamble that the majority of flash emission potential is created due to the initial pressure drop when production is dumped from the separator to the first tank. It is also inconsistent with the technical reality that applies to these systems. Tank battery vapors are generated in three ways: thermodynamic flashing when the liquids change from higher to lower pressure; working loss when liquids flow into the storage vessel displacing vapors within the vessel; and breathing loss due to heating and cooling cycles. Under the EPA's theory, the remaining tanks in a tank battery are limited to working and breathing loss as production is transferred from one atmospheric tank to another. The reality, however, as described above, is that when tank batteries share a common vapor recovery system and control, the vapors generated by the initial pressure differential equalize across the connected vessels because the low restriction allows the vapor to flow more easily to the nearby tanks than to the distant flare(s) or combustor(s). Thus, the vapors – and emission potential – equalize throughout the entire tank battery despite being generated in the first tank receiving liquids. Accordingly, under this type of configuration, the most accurate way to determine each individual tank's PTE is to average throughput and PTE across the tank battery.

E. The EPA's Proposed Methodology Could Produce the Absurd Result that Only One Tank in a Manifolded Series of Tanks is Subject to Subpart OOOOa.

The EPA's proposal to calculate PTE based on each individual vessel in a battery could produce a situation where only one tank in a battery is subject to Subpart OOOOa. And in fact, because the emission factor for each tank in a battery reduces dramatically as production is routed to each successive vessel, the EPA's proposal makes this scenario likely: the first tank in every battery would be subject to the rule while the remainder of the battery is exempt. Under the EPA's proposed scenario, all flash gas attributable to a volume of oil or condensate would be calculated as being emitted from the first tank in series. Subsequent tanks would have no flash gas emissions because the oil or condensate will have depressurized from separator pressure to atmospheric pressure in the first tank. The only emissions from subsequent tanks in series would be due to working and breathing losses. In many cases, particularly for older batteries with lower throughput, working and breathing losses alone will not exceed the applicability threshold of 6 tons VOC per year per tank. Under this scenario, only one tank in a multi-tank battery would be subject to the requirements of Subpart OOOOa – even though the vapor control system for that battery captures and controls emissions from all the tanks in the battery. And operators would have only one tank in a battery subject to Subpart OOOOa's control, design, and recordkeeping and reporting requirements for storage vessel affected facilities, including:

- Route all emissions through a cover and closed vent system to a control device with a 95 percent destruction efficiency.³⁰
- Design and certify the closed vent system to ensure "no detectable emissions."³¹
- Conduct periodic olfactory, visual and auditory inspections to ensure no detectable emissions.³²
- Comply with all applicable recordkeeping and reporting requirements under the rule.³³

Industry, for the sake of operational compliance, safety, and efficiency, often determines applicability on the basis of averaging throughput across all vessels in a battery when utilizing a single, manifolded collection system feeding a control device, and there is a tremendous net emissions benefit when controlling all tanks in a battery, based on throughput averaging, compared to controlling only one vessel based on individual throughput. Averaging and controlling all vessels in a battery – even if it results in the controlled VOC emissions per vessel being less than 6 tons per year – is far better environmentally than controlling only one Subpart OOOO/OOOOa applicable vessel.

It is ultimately not feasible for operators to comply with the above requirements for a *single* storage vessel. Rather, the EPA has readily admitted that if only a single storage tank in a battery were subject to the Rule, "*the owner or operator would have to vent the entire manifold to a control.*"³⁴ Accordingly, under the guise of a "clarification," the EPA effectively proposes to require operators to control and operate an entire battery as subject to Subpart OOOOa based on the theoretical emissions of the first tank.³⁵ And the EPA has entirely failed to take this result into account in its estimates of the amount of affected facilities that would be subject to the rule and the cost-benefit analyses used to support the rule.

F. The EPA's Proposal to Only Include Days in Which Tanks Received Production Would Overstate Potential Emissions and Would Create an Unnecessary and Overly Burdensome Recordkeeping Requirement.

The EPA proposes that "production to a single storage vessel must be averaged over the number of days production was actually sent to that storage vessel, rather than over the entire 30 days."³⁶ For example, the EPA states that "if a storage vessel receives production on 22 of the 30

³⁰ 40 C.F.R. §§ 60.5395a(b)(1), 60.5411a(b)-(d), 60.5412(c)-(d).

³⁵ See Section II.A–B, D.

³⁶ 83 Fed. Reg. at 52,084.

days in the evaluation then the maximum average daily throughput is calculated by averaging the daily throughput that was calculated for each of those 22 days."³⁷ The EPA suggests that it understands this approach would not produce a true average, but that it accurately represents *potential emissions*.³⁸ This is inaccurate. The EPA's proposed approach fails to account for the fact that maximum well production has a limit based on what the wells can produce, and ignores the fact that the same well production will be routed to different tanks in the battery throughout the 30-day period. In this manner, the EPA's proposal requires operators to count the same throughput multiple times for different tanks, resulting in a value greater than the actual possible total production from the wells. Thus, averaging daily throughput for each individual tank based only on the days the tank actually receives production during the 30-day evaluation period would over estimate the total amount of production that each tank could receive over a 30-day window. And when compounded across multiple tanks and extrapolated across an entire year, this approach would significantly overestimate the volume of flow to the tanks as a whole.

G. The EPA Cannot Apply its Proposed Amendments Retroactively.

Contrary to the EPA's suggestion, its proposed amendments related to storage tank applicability represent far more than a "proposed clarification."³⁹ Rather, the EPA's proposed amendments represent a fundamental shift in how many operators have interpreted and applied both Subparts OOOO and OOOOa; an interpretation grounded in the language of the regulation and numerous prior statements by the EPA. For this reason, if the EPA retains its proposed amendments regarding the process for determining storage tank applicability (either in part or in full), the EPA should apply the new definitions and interpretations on a prospective basis only.⁴⁰

As a threshold matter, the EPA itself acknowledges in the proposed reconsideration amendments that it was unclear in its prior rulemakings whether operators could average emissions across a tank battery to determine applicability. Specifically, the EPA stated, "[w]hile the EPA was clear that emissions are not to be averaged over the 30-day period, *we were less clear at the time as to what averaging was allowed* when we used the term 'maximum average daily throughput.' Therefore, we propose to further clarify in this notice when and how daily production may be averaged in determining daily throughput."⁴¹ And the rule language itself nowhere states that operators may not average emissions across a tank battery (particularly a controlled tank battery) in order to determine applicability (nor does it line up with the realities of tank batteries that share common vapor control systems, making it all the more difficult to pull this interpretation out of the rule text). The rule language states only that "[t]he potential for VOC emissions must be calculated *using a generally accepted model or calculation methodology*, based on the maximum average daily throughput determined for a 30-day

⁴¹ 83 Fed. Reg. at 52,084 (emphasis added).

period."⁴² Thus, by acknowledging that most operators have chosen to average emissions across tank batteries, the EPA is acknowledging that this is a generally accepted calculation methodology and that it was reasonable for operators to interpret the regulation in this manner.⁴³ Accordingly, the Independent Producers request that if the EPA retains any portion of its proposed amendments regarding the methodology for determining storage tank applicability, the EPA should make clear in the final rule that those regulatory changes apply on a prospective basis only to sources new or modified after a date certain. Of note, the proposal open for comment addresses only revisions to Subpart OOOOa and does not purport to revise the language of Subpart OOOO. However, because of the similar (and in many cases identical) nature of the language within Subparts OOOO and OOOOa, revisions to Subpart OOOOa could be interpreted to require similar application of Subpart OOOO. All of the concerns related to retroactivity of Subpart OOOOa apply equally to Subpart OOOO and present an even greater legal challenge given that Subpart OOOO is not open for revision at this time.

Limiting any adopted amendments to prospective application is particularly important in this instance because the evaluation period for many facilities potentially subject to the rule would have occurred during the first 30-day production period. Thus, to comply with the EPA's proposed change, operators would need to have records for throughput to each individual tank (not battery) for the first 30-day period of production for each storage vessel dating back to September 2015 for Subpart OOOOa and to August 2011 for Subpart OOOO.⁴⁴ Given that operators reasonably and rationally interpreted the rule to allow them to apply an averaging methodology for determining storage tank emissions, it would be unrealistic to now require operators to have the type of records the EPA enumerates in the proposed reconsideration amendments.⁴⁵ Furthermore, the EPA cannot retroactively apply the new or modified source standards to existing sources through a change in interpretation without establishing a new date after which that interpretation would apply to new and modified sources.

H. Definition of Legally and Practically Enforceable Limits.

The EPA proposes to impose additional limits on what constitutes a "legally and practically enforceable limit" for purposes of determining storage tank PTE.⁴⁶ Specifically, the EPA purports (through language in the preamble of the proposed amendments alone) to require that "any limit on capture and control efficiency from storage vessels must include sufficient

⁴² 40 C.F.R. § 60.5365a (emphasis added).

⁴³ See *Gen. Elec. Co. v. U.S. E.P.A.*, 53 F.3d 1324, 1329 (D.C. Cir. 1995) (noting that in determining whether a "regulated party received, or should have received, notice of the agency's interpretation," courts will look first to the plain language of the regulation).

⁴⁴ Even if the EPA were to adopt some or all of its proposed amendments to Subpart OOOOa, the Independent Producers would oppose similar revisions to Subpart OOOO. But the Independent Producers also acknowledge the reality that the EPA's proposal calls into question industry's interpretation of the relevant provisions under both rules.

⁴⁵ See 83 Fed. Reg. at 52,084 (describing proposed methodology for determining individual tank throughput); *id.* at 52,085 (proposed recordkeeping requirements for demonstrating applicability determination).

⁴⁶ *Id.*

monitoring to timely identify and repair emissions from storage vessels."⁴⁷ This language raises significant concerns and represents a material departure from longstanding EPA practice. Specifically, the EPA's proposal to put additional parameters on what constitutes a "legally and practically" enforceable limit: (1) conflicts with prior EPA statements during Subpart OOOO rulemakings; (2) conflicts with traditional EPA practice to defer to states to determine appropriate mechanisms for limiting PTE; (3) raises concerns about how this new interpretation/approach would apply in the Title V and New Source Review ("NSR")/Prevention of Significant Deterioration ("PSD") context where operators are relying on the same control requirements to limit their PTE; (4) raises significant concerns about retroactive application; and (5) ignores that the LDAR requirements for fugitive components under Subpart OOOOa are not tied to storage-tank applicability and apply regardless of whether a storage tank is an affected facility under the rule.

The EPA suggests that its proposal to impose additional criteria on what constitutes a legally and practically enforceable limit is grounded in the EPA's requirement that enforceable limits meet "certain enforceability criteria."⁴⁸ The Independent Producers disagree that the EPA's enforceability criteria requires the heightened standard proposed by the EPA. The EPA first announced its "enforceability criteria" in 1995.⁴⁹ The 1995 Guidance enumerates only three enforceability criteria for permit conditions: "(1) a technically accurate limitation and the portions of the source subject to the limitation; (2) the time period for the limitation (hourly, daily, monthly, annually); and (3) the method to determine compliance including appropriate monitoring, record keeping and reporting."⁵⁰ And "for rules and general permits that apply to categories of sources, the EPA established that "practical enforceability additionally requires that the provision [1] identify the categories of sources that are covered by the rule; [2] where coverage is optional, provide for notice to the permitting authority of the source's election to be covered by the rule; and [3] recognize the enforcement consequences relevant to the rule."⁵¹ Since the EPA promulgated the 1995 Guidance, the EPA has consistently interpreted this provision to mean that state regulations that are "enforceable as a practical matter," will be considered sufficient to limit a facility's PTE.⁵² This means that the permit conditions or regulations must include "monitoring, recordkeeping, and reporting requirements sufficient to enable regulators and citizens to determine whether the limit has been exceeded and, if so, to take appropriate enforcement action."⁵³ Here, the state regulations and permits relied upon by

⁵¹ *Id.*

⁵² See *In the Matter of Hu Honua Bioenergy, LLC*, 2016 WL 7489673, at *20; EPA, Interim Policy on Federal Enforceability of Limitations on Potential to Emit, 3 (Jan. 22, 1996) ("[T]he term 'federally enforceable' should now be read to mean 'federally enforceable or legally and practicably enforceable by a state or local air pollution control agency.'").

⁵³ *Hu Honua Bioenergy, LLC*, 2016 WL 7489673, at *20 (internal quotations omitted).

industry in calculating PTE for purposes of Subpart OOOO and OOOOa more than satisfy this standard.

For example, in October 2013, following the EPA's publication of Subpart OOOO, the Colorado Department of Public Health and the Environment ("CDPHE") published internal guidance on the "Interpretation of 'Practically Enforceable' Limits for Storage Vessels Addressed under Subpart OOOO ("CDPHE Guidance"). Under the CDPHE Guidance:

[A]n oil and gas storage vessel with an associated and properly operating flare or other commonly-recognized emission control device may take credit for the emissions reductions achieved by that control device when evaluating if the storage vessel is an "affected facility" where the control device is required through: (1) Colorado Air Quality Control Commission regulations (i.e., Regulation No. 7 Sections XII or XVII); (2) Colorado Oil and Gas Conservation Commission (COGCC) regulations; (3) Enforcement documents, such as a Compliance Order on Consent issued by an air authority such as the Division or EPA; (4) Federal regulations (i.e., NSPS or MACT); or (5) Local air quality requirements or regulations.⁵⁴

This interpretation was the correct one: all of these regulatory mechanisms require the continuous control of emissions through an emission control device and impose recordkeeping and reporting obligations on the operator to allow the agency to determine compliance. Importantly, operators relied on this regulation based on this interpretation. Similarly, relying on the EPA's consistent interpretation of "legally and practically enforceable limits," operators around the country rationally interpreted Subparts OOOO and OOOOa to allow them to account for state regulations and permit conditions requiring the control of storage tanks when calculating PTE for purposes of Subparts OOOO and OOOOa applicability. In fact, as discussed above, in the preamble to the proposed 2013 amendments to Subpart OOOO, EPA evaluated eleven states with significant oil and gas production to determine which had storage tank control requirements that operators could take into account when determining PTE: Alaska, California, Colorado, Kansas, Louisiana, Montana, North Dakota, New Mexico, Oklahoma, Texas, and Wyoming.⁵⁵ Based on its evaluation of these regulations, the EPA subtracted storage vessels in states with storage tank control requirements "from the overall count of storage vessels that would be subject to the final rule."⁵⁶ Since that evaluation, additional states have developed control requirements that appropriately establish legally and practically enforceable limits. Thus, the EPA's new approach in the proposed reconsideration amendments not only conflicts with its traditional and consistent practice; it also threatens to subject existing sources to performance standards without sufficient notice.⁵⁷

The EPA's suggestion that existing state regulatory programs and permit conditions no longer meet the definition of "legally and practically enforceable" also casts uncertainty on other

⁵⁴ CDPHE Guidance at 1.

CAA programs. Operators currently rely on the same regulations and permit conditions used to restrict PTE for Subparts OOOO and OOOOa to remain a synthetic minor under the EPA's Title V and PSD/NSR programs. The EPA's proposal thus causes confusion and casts doubt on thousands of permits under these programs around the country.

Based on the above, the Independent Producers suggest that EPA remove its proposal to impose additional parameters on enforceable limits under Subpart OOOOa and, consistent with longstanding practice, continue to defer to states to determine which of their programs satisfy the standard. However, in the alternative, if the EPA chooses to retain its proposal to redefine what constitutes an enforceable limit under Subpart OOOOa, the EPA should: (1) apply its new interpretation prospectively; (2) offer detailed guidance to operators and states on what constitutes a legally and practically enforceable limit under the rule; (3) clarify the effect of its new interpretations in regard to other CAA programs; and (4) give states sufficient time to revise their programs and permits before making this portion of the rule effective.

Finally, the Independent Producers emphasize that the EPA's concerns regarding legally and practically enforceable limits for sources potentially subject to Subpart OOOOa are unfounded because the EPA has ignored that Subpart OOOOa requires compliance with its LDAR requirements regardless of whether the requirements related to storage tanks apply. As noted above, the EPA states in the reconsideration amendments that "any limit on capture and control efficiency from storage vessels must include *sufficient monitoring to timely identify and repair emission from storage vessels* to ensure the limit on capture and control efficiency is consistently achieved."⁵⁸ Through this language, the EPA appears to be suggesting that legally and practically enforceable limits under state regulations and permits must include requirements similar to those imposed under a leak detection and repair program in order for operators to utilize the controlled PTE in determining applicability of the storage tank requirements in Subpart OOOOa. However, this suggestion ignores that the standards for storage vessels under Subpart OOOOa are focused on the installation of a control device, cover, and closed vent system to reduce VOC emissions from the storage vessel.⁵⁹ Another Section, § 60.5397a, imposes leak detection and repair requirements on the affected facility defined as "the collection of fugitive emissions components at a well site."⁶⁰ This includes all "valves, connectors, pressure relief devices, open-ended lines, flanges, covers and closed vent systems not subject to § 60.5411a, [and] *thief hatches or other openings on a controlled storage vessel not subject to § 60.5395a*."⁶¹ In other words, storage vessels "not subject" to the control requirements of § 60.5395a – in many cases because they are subject to a corresponding state control requirement – must still implement an LDAR program for fugitive emissions under the rule. Therefore, it is entirely unclear what the EPA hopes to achieve by requiring similar requirements under state programs in order for operators to be able to take those regulations and conditions into account when calculating PTE for purposes of Subpart OOOOa.

⁶¹ *Id.* at § 60.5430a (emphasis added).

I. Proposed Recordkeeping Requirements for Storage Vessels.

1. The EPA's enhanced recordkeeping requirements for affected facilities are unduly burdensome and unnecessary.

The EPA proposes a significant number of new recordkeeping requirements – mainly to correspond with the methodology that the EPA now proposes that operators utilize in calculating emissions from individual storage vessels.⁶² As noted above in Section III.D, the EPA proposes a methodology of estimating emissions and assessing throughput to individual tanks that is inconsistent with many operators' current practices or has any technical basis. Because each of these recordkeeping requirements implicates operators' ability to generate the information required, the Independent Producers have significant concerns with the records proposed to be maintained.

Of particular note, the EPA proposes that operators document the operational configuration of the tank, including recordkeeping of the specific storage vessel that production was routed to for each day in the 30-day production period. Such a requirement indicates that the EPA fundamentally misunderstands how tank systems function and creates an overly burdensome new record requirement that operators neither maintain nor see any value in maintaining. Importantly, operational configurations of tank batteries are not static and can change (even on a day-to-day basis). The tank that first receives production one day may be the second tank to receive production the next day. Thus, it is not feasible to maintain or track each different configuration or track the days on which a specific configuration was in operation. And there is no value to doing so for controlled tanks that are manifolded together as described above.

Accordingly, consistent with the Independent Producers' Comments throughout, and in Section III.I in particular, the Independent Producers suggest that the EPA remove the proposed recordkeeping requirements to the extent they would require operators to document the operational configuration of the tank or document throughput to individual vessels in a tank battery.

2. The EPA should not impose recordkeeping requirements on facilities not subject to the rule.

In the Reconsideration Rulemaking, the EPA is also soliciting Comments "on specific recordkeeping requirements that would support the applicability determination for each individual storage vessel *regardless of whether that storage vessel is determined to be an affected facility*."⁶³ According to the EPA, "[t]his is because recordkeeping is necessary to be able to verify that rule applicability was appropriately determined in accordance with the regulatory requirements."⁶⁴ Such an approach is entirely inconsistent with traditional NSPS requirements. Operators are required to determine compliance with an NSPS. Operators, upon

⁶² See 83 Fed. Reg. at 52,085.

⁶³ 83 Fed. Reg. at 52,085 (emphasis added).

⁶⁴ *Id.*

request and in certain circumstances, may be required to demonstrate the basis for their conclusion that a facility is not subject to an NSPS. Operators perform this assessment in some way, shape, or form for every NSPS. However, the NSPS itself – which is only applicable to affected facilities – should not in this one case have an independent recordkeeping requirement applicable to non-affected facilities.⁶⁵

The EPA's proposed amendment could create confusion and raises significant enforcement concerns. Operators will typically look first to the applicability section of an NSPS, and if it is determined that a specific facility is not subject to the rule, they look no further (*e.g.*, into the recordkeeping sections applicable only to affected facilities).

Finally, the EPA's proposal raises concerns about the potential for retroactive application (as discussed in further detail above). The EPA says that it is clarifying a rule that has been in existence for years, but is apparently expecting operators to have records that would demonstrate compliance now with the EPA's new interpretation. At a minimum, if the EPA includes recordkeeping for non-affected facilities (which the Independent Producers believe it should not), then the EPA should clarify in the final rule that this new recordkeeping requirement will apply only on a prospective basis.

IV. AMEL – EMERGING TECHNOLOGY

America is on the cusp of new breakthroughs that can bring dramatic improvements to air quality at lower cost. OGI was an important step toward lower emissions, but far from the last step. Less expensive and more effective monitoring technologies will accelerate the production of clean domestic energy, helping to deliver a healthy environment and a healthy economy. The EPA must revise the AMEL provisions of Subpart OOOOa to unlock the benefits of these emerging technologies.

A. The Independent Producers Support the Options in the Proposed Rule to Use Modeling, to Test Technologies in a Controlled Test Environment, and to Allow Manufacturers/Vendors to Apply for Approvals.

1. Modeling

Independent Producers strongly support the inclusion of modeling, in addition to limited field data, to demonstrate the performance of a specific technology. This is a preferred and recommended option to the onerous requirement to gather 12 months of field data. The 2018 Interstate Technology and Regulatory Council ("ITRC") paper states, "Computer modeling is highly valuable for evaluating emission reduction objectives due to the probabilistic nature of emission rates."⁶⁶ The paper also states, that "computer-based modeling, coupled with empirical

⁶⁵ See 40 C.F.R. § 60.1(a) ("[T]he provisions of this part apply to the owner or operator of any stationary source which contains an affected facility.").

⁶⁶ Interstate Technology and Regulatory Council ("ITRC"). 2018. Evaluation of Innovative Methane Detection Technologies. Section 5.2 Design Elements. Methane-1. Washington D.C.: Interstate Technology and Regulatory Council, Methane team. <https://methane-1.itrcweb.org>

validation of model accuracy, is a potential solution to rigorously evaluate application efficacy under the most likely encountered meteorological and site conditions.⁶⁷ The Fugitive Emissions Abatement Simulation Toolkit ("FEAST") model is a virtual gas field simulator that predicts emission reductions of various leak detection and repair programs. An effective demonstration of equivalency could include an empirical evaluation of an application at a structurally complex site such as a gathering compressor station over a time period such as twelve months that assesses performance under a wide range of meteorological conditions. If a computer model can accurately predict the detection limit and response time for different sources as a function of environmental parameters, then a probabilistic model can be used to simulate performance at other sites. This approach could allow a scientifically rigorous determination of equivalency while minimizing the number of sites required for field testing.⁶⁸ Additionally, modeling is highly valuable in that it allows for comparison of the "end game" of equivalent emissions reductions, *i.e.* allows for comparison of two approaches/work practices rather than specific technology detection thresholds.

Further, the EPA used modeled simulations when they simulated the frequency and work practice to detect leaks from equipment ("OGI AWP").⁶⁹ The EPA used a Monte Carlo model to evaluate and approve the use of OGI as an alternative work practice ("AWP") for fugitive emissions monitoring.⁷⁰ "In developing the AWP, the EPA sought to design a program for using the optical gas imaging instrument that would provide for emissions reductions of leaking equipment at least as equivalent as the current work practice. To do so, we used the Monte Carlo model for determining what leak rate definition and what monitoring frequency were necessary for the AWP."⁷¹ At no point in its approval of OGI did the EPA require site-specific modeling.

We strongly urge the EPA to apply the same logic to AMEL equivalence demonstrations. There is no reason why rigorous statistical modeling, combined with real-world field data and thorough documentation and recordkeeping, should not be sufficient for EPA to make a reasoned decision on broadly approving a new technology.

a. Controlled test environment.

Use of a controlled test environment, such as Colorado State University's Methane Emissions Technology Evaluation Centre ("METEC") to gather field data on the performance of various leak detection technologies and compare their capabilities to current approved methods, such as OGI, would greatly streamline the process of determining equivalence, as well as the lengthy CAA Section 111(h) application and approval process. The Independent Producers appreciate the EPA including this option in the proposal and further recommends that a facility such as METEC be recognized by the EPA as a facility where all suitable technologies could be tested for equivalency. The team METEC is currently working to establish a baseline for OGI for this very purpose. In fact, the EPA has funded work at METEC toward developing the

⁶⁷ *Id.*

⁶⁸ *Id.*

⁶⁹ Alternative Work Practice to Detect Leaks from Equipment Final Rule, 73 Fed. Reg. 78201 (add date)

⁷⁰ 73 Fed. Reg. at 78,201.

⁷¹ *Id.*

baseline for OGI. Testing a new technology against a clear established baseline and following a pre-set methodology for testing would provide consistency and confidence in the process. If manufacturers are aware of the baseline emissions reduction for OGI they would clearly know how their technology must be utilized in an LDAR program to be deemed equivalent. As a result this would streamline the process and allow new technologies to successfully navigate this application and approval process and be deployed faster which, in turn, would result in reducing fugitive emissions faster.

The ITRC paper referenced above supports this concept and states:

[c]ontrolled releases under field conditions are ideal for systems with emission source objectives because they can assess the accuracy of source quantification and/or localization under realistic meteorological conditions. Long-term testing at field sites allows controlled releases to be tested under a diversity of meteorological conditions. Performing multiple controlled releases under each set of conditions can be used to calculate the probability of detection as a function of emission rates and other relevant conditions such as wind speed.⁷²

Therefore, gathering field data at a facility such as METEC would prove extremely useful and could effectively take the place of gathering field data at an active oil and gas well site. The API recommends that testing technologies in a controlled test environment, in addition to modeling, will greatly minimize the field data necessary in order to demonstrate the performance of various technologies and achieve approvals.

b. Vendors/manufacturers as applicants for approval of emerging technology.

Vendors/manufacturers of new leak detection technologies are the experts in this advanced, high tech area and are the appropriate person(s) to apply for approval of a technology to be used in compliance with Subpart OOOOa for methane and/or VOC leak detection and Independent Producers appreciates the inclusion of this language in the proposal.

However, the Independent Producers recommend that the operator not be required to be a party to the application and approval process as well. Although the manufacturer/vendor may need to coordinate with an operator to test their technology in the field and obtain data, oil and gas operators are not in the business of, nor are they likely to have the bandwidth, to develop, test, and obtain approvals for methane leak detection technologies.

B. The EPA Should Allow for Basin-Wide Approvals of Emerging Technology for Use in Complying with the Leak Detection Requirements in the Rule

One of the Independent Producers' priority concerns in the proposed Reconsideration Rulemaking is the requirement to apply for the use of emerging technologies on a site-specific level. Outlined below are the technical and legal reasons why this would be an enormous unnecessary burden, not feasible to undertake from an administrative and timing perspective, not effective at showing equivalence to the current method, and will greatly stifle innovation in this

⁷² *Id.*

very dynamic area of technological advancement. Numerous technologies are currently being developed and piloted at oil and gas field sites throughout the country. Many of these state of the art technologies in development can detect leaks faster and more efficiently which will enable the operators to make timely repairs resulting in less fugitive emissions, resulting in a win-win for both the operator and the environment. This recommendation has broad support from environmental groups as well as industry.

1. Site specific variables can be addressed in conditions required for the use of the technology.

In the proposal, the EPA states that "we are not changing the requirement that AMEL's be site-specific because we are aware of the variability of this sector and are concerned that the procedures may need to be adjusted based on site-specific conditions (*e.g.*, gas compositions, allowable emission or landscape).⁷³ There is no logic behind this statement and this reasoning does not withstand scrutiny. First, if a technology is designed to measure methane molecules in the atmosphere, it will measure methane molecules in the atmosphere, plain and simple. It does not matter what the site looks like or what the gas composition is. If there is methane above a certain concentration, the technology should find it; if there is not, it will not.

Further, the EPA can establish clear and consistent parameters under which a technology will be able to detect methane emissions. The approval of the technology could have certain conditions assigned to it that are required to be met in order for the technology to be used at a site, similar to the EPA's technology-based approval for OGI that had minimum/maximum temperatures and minimum/maximum distance parameters required to be present, for example.

Continuous sensors, for example, allow for continuously monitoring a site for leaks and particularly suited for intermittent leaks at very low thresholds. Day or night time is immaterial for detection by continuous sensors. On the other hand, aerial based surveys might have limitations flying at night and may use sunlight as reference and would need to be deployed only during the daytime.

In response to the EPA's mention of landscaping being a site-specific variable, if the landscaping at a particular site is not conducive to the technology employed (*i.e.*, impedes the pathway of the technology to effectively operate, for example) then the technology may not be used at that site. Parameters are required to be met for the proper operation of the specific technology, plain and simple. Again, this could be a condition for the use of a specific technology at a specific site.

In response to the EPA's mention of allowable emissions being a site specific variable, this is completely irrelevant to the case for a site specific approval. Every site has allowable emissions such as some venting that is allowed if under threshold levels. Differentiating allowable venting, for example, from fugitive emissions leaks could arguable be an issue against the approval of any technology but that should not be a reason to disallow approval on a basin-wide level and stifle all development in this important area. An approach where detection may be impacted by allowable emissions may be an approach that is used to direct inspection efforts.

⁷³ Subpart OOOOa Proposed Technical Revisions, 83 Fed. Reg. at 52,080 (October 15, 2018)

Some technologies could be used as a frequent screening tool and may require the operator visit the site with OGI for example to detect the source of the leak(s). But it would flag the large emitter sites and again, enable the operator to find and fix the largest leaks faster.

In the OGI AWP final rule, the EPA stated, "the standard is an alternative to the existing work practice and maybe used in place of the existing work practice where feasible and whenever the owner or operator chooses to do so."⁷⁴ As this language clearly states, OGI received a blanket approval from the EPA but if a particular site did not meet the conditions, then the technology was deemed not feasible that site at that time. Often, Independent Producers' member companies' camera operators determine that they cannot take an accurate OGI survey due to meteorological conditions and they return later when the conditions are within the prescribed OGI parameters.

2. Basin-wide data is necessary to determine equivalency and receive approval per Clean Air Act 111(h).

The technologies being developed have different methane sensitivity thresholds and can operate at different frequencies. For example a spectrometer (*i.e.*, laser based technology) mounted on an airplane can scan over an entire basin in days. It could do these fly-overs more quickly and efficiently than a person using a hand held OGI camera on foot at a site and therefore, could have a higher frequency assigned to it and this would be a feasible alternative. The cost benefit analysis of some of these emerging technologies have been shown to be favorable and a preferred option for some member operators.

In the OGI AWP, the EPA states, "[t]he emission control effectiveness of any work practice is a function of both 1) its ability to detect leakage and 2) the frequency of monitoring. An equivalent work practice may require more frequent monitoring, depending on its mass rate threshold for detecting leaks."⁷⁵

If the fly-over technology has a lower sensitivity threshold, it may only find larger leaks, but it could find these larger leaks faster with a more frequent monitoring schedule.

The EPA further states, "[a] more frequent monitoring requirement becomes necessary because higher mass emission reductions from large leaks, found earlier, are offset by some degree by smaller leaks which go undetected."⁷⁶ Equivalency in Section 111(h)(3) is discussed simply as "a reduction in emissions of any air pollutant at least equivalent to the reduction in emissions of such air pollutant [under the current work practice]."⁷⁷ Based on this standard in

⁷⁴ Alternative Work Practice to Detect Leaks from Equipment Final Rule, 73 Fed. Reg. at 78,204 (Dec. 22, 2008). (emphasis added)

⁷⁵ Alternative Work Practice to Detect Leaks from Equipment Proposed Rule, 71 Fed. Reg. at 17,404 (Oct. 18, 2008).

⁷⁶ *Id.*

⁷⁷ 42 U.S.C. § 7411(h)(3).

the statute, larger leaks found earlier and more frequently should reasonably be able to offset smaller leaks that may not be found as timely.

Further, in referring to OGI in the AWP final rule, the EPA stated, "[t]he results show that the AWP will achieve the *EPA's goal of detecting leaking equipment from which the majority of emissions arise.*"⁷⁸

Therefore, similar to the EPA's approach in the AWP OGI rulemaking, the EPA should focus on basin-wide (or category-wide) mitigation equivalence, not detection equivalence. For example, a one-time aerial-based survey may not be able to detect emissions with the same sensitivity as ground-based technologies, or detection equivalence, but conducting multiple surveys instead of one would mean that any potential fat-tail emission sources are identified faster than a ground-based method. That means more frequent monitoring may provide mitigation equivalence. Mitigation equivalence can only be achieved across many sites, because of the relatively few sites that produce the bulk of emissions. Further, basin-wide approaches are likely to be more accurate in terms of estimating total emission reductions than individual site estimates, given the high variability in individual site emissions. The emission reductions at any given site may differ greatly, but averaged across thousands of sites, the EPA will be able to understand emission reductions with greater confidence.

The EPA can use statistical models such as FEAST to make data-driven decisions about equivalence. The EPA can then incorporate basin-specific emissions data into modeling to ensure that its emission reduction objectives are being met. Making decisions based on aggregated data reduces the uncertainty that comes with site-specific estimates.

In addition, Independent Producers recommend that the site attributes could be obtained from a small number of representative sites in the basin; then that data, coupled with modeling and testing in a controlled test environment would be adequate to determine if equivalency is achieved.

Further, once a technology is approved to be used in a specific basin, all subsequent sites drilled and constructed in that basin going forward will have the opportunity to use that technology, without going through the onerous Section 111(h) application and, approval process for each new site, or groups of new sites all over again. Again, this is not feasible and would stifle development of leak detection technologies.

Therefore, based on this information and the EPA's logic in this previous OGI AWP rulemaking, a basin wide survey is necessary to have a data set that can be deemed equivalent. And once this technology has been deemed equivalent based on emissions reductions achieved in a specific basin, use of the technology in that basin should be the subject of the application for approval. As explained above, the approval could be granted with conditions that would need to be met at each site prior to the technology being used.

⁷⁸ Alternative Work Practice to Detect Leaks from Equipment Final Rule, 73 Fed. Reg. at 78203 (December 22, 2008)

3. Common sense dictates basin-level approval.

CAA Section 111(h) requires that an alternative work practice must first be shown to be equivalent, then be subject to a notice and comment period, and possible public hearing. Gathering the field data and performing modeling, and showing equivalence will be a lengthy process, of at least a year or more. Then the notice and comment period will take months; EPA stated in the Subpart OOOOa final rule that they would make a decision within 6 months of close of the comment period.⁷⁹ Therefore, realistically, this process would take approximately two years. To do this for every single well site, such as a well or wells on a pad or a centralized tank battery would be ludicrous. Neither the regulated community nor the EPA can manage the crush of applications that will be necessary to adopt new technologies through site-specific approval. It would be outrageously lengthy and absolutely no vendor/manufacturer or operator would undertake this fruitless effort.

One of the Independent Producers member company's operations in the Permian Basin in Texas reported 273 well sites subject to Subpart OOOOa LDAR monitoring for 2018. Going through this Section 111(h) process for each of these sites would take 546 years. And then all over again for the subsequent wells this operator is drilling in the Permian Basin every month (with about 3 wells/pad or well site) and building around 4-6 large centralized tank batteries per year that would also require site-specific approval per the current language in the rule.

Common sense clearly dictates that the EPA reconsider this site-specific approach and approve a basin-wide (or category-wide) approach. Not doing so would stifle innovation in this technologically advanced, dynamic area. The environment would be the loser for the life of this rule if EPA allows only handheld OGI cameras or Method 21, both of which will be outdated technologies in a few years, to detect leaks in compliance with Subpart OOOOa.

4. CAA Sec. 111(h)(3) does not constrain basin-wide approvals.

The EPA should provide a procedure for approving an AMEL under Subpart OOOOa for categories of sources, rather than limit an AMEL to an inefficient and unworkable source-by-source application. The structure and language of Section 111 and EPA's decision to allow for similar flexibilities under other CAA provisions confirm that applying an AMEL to source categories is appropriate and lawful.

Section 111 calls on the Administrator to list "categories of stationary sources" that "cause[], or contribute[] significantly to, air pollution which may reasonably be anticipated to endanger public health or welfare."⁸⁰ The Act then calls on the Administrator to promulgate and subsequently revise every eight years, if appropriate, "standards of performance for new sources within such source category."⁸¹ The Act defines a standard of performance for purposes of Section 111 as:

⁷⁹ Subpart OOOOa Final Rule, 81 Fed. Reg. at 35,861 (June 3, 2016)

⁸⁰ 42 U.S.C. § 7411(b)(1)(A).

⁸¹ *Id.* § 7411(b)(1)(B).

a standard for emissions of air pollutants which reflects the degree of emission limitation achievable through the application of the best system of emission reduction which (taking into account the cost of achieving such reduction and any nonair quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated.⁸²

In the event it is not feasible to establish such a standard, Section 111(h)(1) authorizes the Administrator instead to "promulgate a design, equipment, work practice, or operational standard, or combination thereof."⁸³ Section 111(h)(1) does not refer to categories of sources or individual sources, but because a Section 111(h) standard is intended to replace a standard of performance applicable to an entire source category, the logical inference is that Section 111(h) standards also apply to source categories. Section 111(h)(3) provides for an AMEL when:

after notice and opportunity for public hearing, any person establishes to the satisfaction of the Administrator that an [AMEL] will achieve a reduction in emissions of any air pollutant at least equivalent to the reduction in emissions of such air pollutant achieved under the requirements of [section 111(h)(1)].⁸⁴

On the face of this language, because any AMEL will serve as a replacement for a category-wide 111(h)(1) standard, any demonstration that an AMEL will achieve an emission reduction at least equivalent to a 111(h)(1) standard could reasonably be made on a category-wide basis and be applied to an entire source category.

Section 111(h)(3) also states, however, that once a successful equivalency demonstration has been made, "the Administrator shall permit the use of such alternative by the source for purposes of compliance with this section with respect to such pollutant."⁸⁵ This provision's authorization of source-specific AMEL applications should not be interpreted to preclude the EPA's authorization of an AMEL on a source category-wide basis. Indeed, provided an adequate demonstration for a single source within a source category can be made and it can be established that there are no material differences between that source and the other sources in the category that would render the AMEL less than equivalent to a Section 11(h)(1) standard, there is no reason based on the statute to prohibit category-wide application of AMEL. Indeed, any other number of approaches, including a more generalized approach that does not focus on individual sources, for making an adequate category-wide demonstration under Section 111(h)(3) may be available, and EPA should evaluate them on a case-by-case basis.

Allowing for source category-wide AMEL determinations would be consistent not only with the overall structure of Section 111 and its focus on category-wide standards under Sections 111(b) and 111(h)(1); it is also consistent with the limitation prohibiting the EPA from imposing

⁸² *Id.* § 7411(a)(1).

⁸³ *Id.* § 7411(h)(1).

⁸⁴ *Id.* § 7411(h)(3).

⁸⁵ *Id.*

specific technological emission reduction requirements pursuant to section 111. Section 111(b)(5) states:

Except as otherwise authorized under subsection (h) ..., nothing in this section shall be construed to require, or to authorize the Administrator to require, any new or modified source to install and operate any particular technological system of continuous emission reduction to comply with any new source standard of performance.⁸⁶

Section 111(h)(1) allows the EPA, under limited circumstances, to impose a standard "which reflects the best technological system of continuous emission reduction." Section 111(h)(3) serves as a safety valve on that authority and thereby functions to further the policy set out in Section 111(b)(5). To give full effect to that policy, the EPA should allow for category-wide AMEL demonstrations.

Adopting such an interpretation for Section 111(h)(3) would also be consistent with the policy EPA has adopted for the nearly identical provision in Section 112(h)(3), which authorizes an AMEL under the provisions of the CAA governing national emission standards for hazardous air pollutants. The EPA's regulation implementing Section 112(h)(3) recognizes that the EPA is authorized to approve an AMEL for "source(s) *or category(ies) of sources* on which the alternative means will achieve equivalent emission reductions."⁸⁷ Given the similarities between the programs authorized under Section 111 and Section 112 and, in particular, the similarity of Section 111(h)(3) and 112(h)(3), the EPA should adopt its policy of applying an AMEL to source categories for Section 111(h)(3) in the same manner as it has done with respect to Section 112(h)(3).

Moreover, the EPA has adopted similarly flexible approaches under other provisions of the CAA. For example, under the Act's visibility provisions, the EPA must require states to include in their state implementation plans measures reflecting "best available retrofit technology" ("BART") for certain "major stationary sources."⁸⁸ The Act further states that BART must control emissions "from such source," and defines BART as taking into account, among other things, "any existing pollution control technology in use at the source" and "the remaining useful life of the source."⁸⁹ Despite the focus of the statutory language on determinations for individual sources, the EPA's rules allow the EPA and the states to authorize BART alternatives that can apply to groups of sources and that allow emission averaging across sources, even over wide regions, in lieu of imposing source-specific emission limits or source-specific alternatives to such limits.⁹⁰ The courts have consistently affirmed the authority of the EPA and the states in this regard.⁹¹ If alternatives to emission limits (or work practice standards)

⁸⁶ *Id.* § 7411(b)(5).

⁸⁷ 40 C.F.R. § 61.12 (emphasis added).

⁸⁸ 42 U.S.C. § 7491(b)(2)(A).

⁸⁹ *Id.* § 7491(b)(2)(A), (g)(2).

⁹⁰ 40 C.F.R. § 51.208(e)(2).

⁹¹ See, e.g., *Util. Air Regulatory Grp. v. EPA*, 471 F.3d 1333 (D.C. Cir. 2006); *Central Ariz. Water Conserv. Distr. v. EPA*, 990 F.2d 1531 (9th Cir. 1993).

for groups of sources under these provisions are permissible despite the continued references to the term "source," then surely a source category-wide AMEL is permissible under Section 111(h)(3).

In regard to frequency specifically, there is no legal impediment to demonstrating that an AMEL is equivalent to a Section 111(h)(1) standard based on differences between the AMEL and the standard against which it is being evaluated – such as differences in the frequency (*e.g.*, annual, semi-annual, quarterly) over which the monitoring or other requirements must occur. The current regulations for implementing Subpart OOOOa state that the EPA "may condition permission [to use an AMEL] on requirements related to the operation and maintenance of the alternative means."⁹² Such requirements could easily include frequency of the deployment or operation of the AMEL.

V. AMEL – STATE EQUIVALENCY

A. The EPA Should Recognize the Approved State Programs as Wholly Equivalent to Subpart OOOOa LDAR Program and Fully Delegate the Implementation of the LDAR Monitoring Provisions to These Respective States.

Based on the EPA's state LDAR program equivalency guidance document provided with this rulemaking, the EPA explained that they analyzed the sensitivity thresholds and monitoring frequencies of approved technologies in a number of state programs, as well as other program requirements and, based on all of these variables combined, deemed these various state programs equivalent to Subpart OOOOa LDAR program.⁹³ However, the EPA is requiring operators to use the fugitive emission component definition from Subpart OOOOa, in addition to the reporting and monitoring plan. Many Independent Producers members are required to comply with state permit requirements and therefore, are currently implementing both the state and federal LDAR programs concurrently and the differing required recordkeeping and reporting requirements, as well as Subpart OOOOa's monitoring plan. This is a very burdensome duplicative administrative burden with no added benefit for the environment.

Under the well-established premise of cooperative federalism, the EPA should recognize these programs in full, including the states' recordkeeping and reporting requirements. The states have recordkeeping and reporting to ensure compliance with their programs and the EPA should give proper deference to states for compliance assurance for their state program. If the state program is not adequate in the EPA's opinion, then the EPA needs to address this issue with the states.

Complying with two different recordkeeping and reporting schemes on the same site(s) is an enormous administrative burden with no added environmental benefit. And requiring the federal reporting (which would require some Subpart OOOOa recordkeeping requirements to be

⁹² 40 C.F.R. § 60.5398a(a).

⁹³ EPA's Memo. *Equivalency of State Fugitive Emissions Program for Well Sites and Compressor Stations to Proposed Standards at 40 CRF Part 60, Subpart OOOOa* (April 12, 2018).

met in order to comply with the federal reporting), and monitoring plan defeats the purpose and any benefit from the EPA approving these state programs in the first place.

Cooperative federalism is a central tenet of the CAA. Over the course of its fifty year history, the Act has evolved first from a set of general principles intended to guide States as they undertook regulation of air pollution sources, to an extensive number of more targeted standards often prescribed by the federal government in the first instance and then implemented by the states. The principle that the States and the federal government will work in tandem to protect the nation's air resources is embodied throughout the Act. Congress, in Section 101(a)(3) of the Act, declared air pollution control to be "the primary responsibility of States and local governments,"⁹⁴ with the federal government providing "financial assistance and leadership."⁹⁵

For example, pursuant to Section 110 of the CAA, while the EPA develops the national ambient air quality standards,⁹⁶ states develop plans, called state implementation plans, to meet those standards. In that context, the U.S. Supreme Court has made clear that "[t]he Act gives the Agency no authority to question the wisdom of a State's choices of emission limitations if they are part of a plan which satisfies the standards."⁹⁷ Similarly, under the CAA's visibility provisions, states have broad leeway to develop plans to combat regional haze that the EPA cannot second-guess if the states have considered the statutory factors.⁹⁸

Section 111, the provision at issue here, fits squarely within the cooperative federalism tradition, with section 111(c) expressly calling on states to develop "a procedure for implementing and enforcing standards of performance for new sources" and calling on the Administrator to delegate "any authority he has ... to implement and enforce such standards."⁹⁹ The Supreme Court has affirmed that these cooperative principles are the heart of the CAA again and again.¹⁰⁰

State LDAR programs are precisely the sort of regulation over which states have special expertise, and they are proper subjects of state control.

VI. RECORDKEEPING AND REPORTING REQUIREMENTS

The Independent Producers appreciate the changes the EPA has made to the Subpart OOOOa recordkeeping and reporting requirements, but we continue to believe further streamlining is necessary to reduce financial burden to operators, especially in those situations

⁹⁴ 42 U.S.C. § 7401(a)(3).

⁹⁵ *id.* § 7401(a)(4).

⁹⁶ *see* 42 U.S.C. §§ 7408, 7409.

⁹⁷ *Train v. Natural Res. Def. Council, Inc.*, 421 U.S. 60, 79 (1975).

⁹⁸ *Am. Corn Growers Ass'n v. EPA*, 291 F.3d 1, 8 (D.C. Cir. 2002).

⁹⁹ 42 U.S.C. § 7411(c)(1).

¹⁰⁰ *See, e.g., Whitman v. Am. Trucking Ass'ns*, 531 U.S. 457, 470 (2001) ("It is to the States that the CAA assigns initial and primary responsibility for deciding what emissions reductions will be required from which sources."); *Union Elec. Co. v. EPA*, 427 U.S. 246, 269 (1976) ("Congress plainly left with the States, so long as the [NAAQS] were met, the power to determine which sources would be burdened by regulation and to what extent.").

where the requirements do not enable the Agency to determine compliance. In these instances, we maintain that the increased financial burden caused by the excessive reporting and recordkeeping is unjustifiable. The Independent Producers believe further reductions and streamlining to the recordkeeping and reporting requirements are essential to the creation of an effective rule.

A. Well Completions

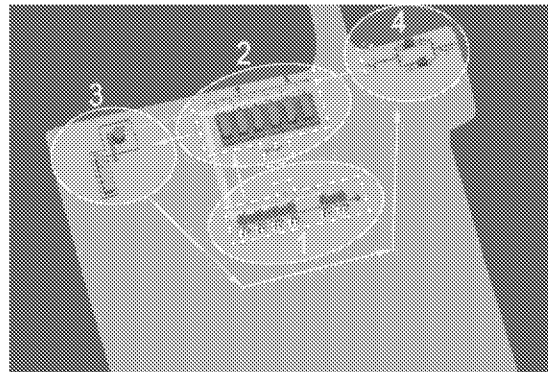

Section 60.5420a(b)(2) lists recordkeeping and reporting requirements for flowback routed through *permanent* separators. However, the presence of a permanent separator that was installed and operated from the onset would technically indicate that the flowback process never actually occurred making any recordkeeping and reporting requirements in these situations unnecessary and overly burdensome. The presence of a permanent separator indicates production has begun. The lack of a temporary separator and the absence of flaring and/or venting to accommodate emissions during flowback eliminates the necessity for any type of recordkeeping and reporting beyond simply acknowledging that the well went directly into production and no flowback occurred at that location.

B. Observation Path

It is most typical that the engineering footprint of equipment at a well site remains the same from site to site as the operating process does not change. This is most particular for well sites within the same basin. To that extent, it is rather redundant to require an observation path depicting the footpath of the surveyor when the inspection would necessarily follow to process flow of the equipment in order to capture all the potential leaks. For example, below are the actual Observation Paths of two independent well sites with the same process flow. As depicted, the footpath of the surveyor always follow the same sequence in terms of the process equipment.

Well Site A

Well Site B

In lieu of maintaining an Observation Path and Site Map for every well site, we would propose a description be included in the company's Monitoring Plan instructing the surveyor to follow the process flow. An example is as follows:

Perform an inspection of the following equipment in the sequence as follows: Well heads → Separators → Tanks → meter area. For each equipment, perform a 360 degrees inspection before proceeding to the next.

For Example - In Lieu of an observation path, we propose a description of how each "type" of equipment will be monitored via a description and location of each component being monitored.

C. Pneumatic Pumps

We recommend removing all recordkeeping and reporting requirements associated with the inspection of covers as referenced in §60.5416a(a). Covers are unique to storage vessels and have no reason to be listed in pump requirements.

D. Low Production Wells (Wildcat Wells, Delineation Wells, Low Pressure Wells, and Wells with GOR less than 300 scf/bbl)

The EPA continually fails to consider the massive financial, resource allocation, and administrative impacts resulting from the excessive amount of prescriptive requirements assigned to production facilities. What is more distressing is that these overly burdensome requirements are applied to all facilities independent of the level of production. The EPA seems to consider minor source production facilities on a level playing field with refineries and infinitely more complex operations that have thousands more components than even the largest applicable sources covered by this rule. The Independent Producers understand low production source (< 15 BOE) exemptions are being reconsidered¹⁰¹ and urge The EPA to follow through with such an exemption, specifically concerning LDAR requirements and the associated recordkeeping and reporting. High volume recordkeeping, on par with large refineries, is not necessary and completely unjustified for these diminutive, financially sensitive sources.

E. Storage Tanks

The EPA is soliciting comments on the type of records necessary to ensure proper calculation of VOC emissions and maximum daily average (*i.e.*, daily measurements, liquid height measurements, start and end dates for each production period, number of days production was routed to a particular storage vessel, load slips when automated readings are unavailable, documentation of the operational configuration of the tank/tank battery, etc.). The EPA is also seeking comment on the perceived recordkeeping burden to operators.

It is unclear how the newly proposed maximum daily average calculations will help control, or reduce, emissions from storage vessel affected facilities, especially with respect to controlled tanks and/or tanks that are manifolded together. Consequently, the increased recordkeeping and reporting requirements that accompany this proposal are overly burdensome and without environmental benefit. Any increased recordkeeping and reporting requirements that result from disallowing emissions averaging over the entire tank batteries that share a common control device, or vent, are unnecessary. Furthermore, it is unclear if operators, especially small operators, even have the capability to monitor and record individual storage

¹⁰¹ See Docket ID No. EPA-HQ-OAR-2010-0505-7730.

vessel throughputs as described in the EPA's proposed scenarios. Tank unloading operations are tracked by the total volume of liquids removed from the facility, as are the tank overheads in the shared manifold system and/or closed vent system ("CVS"), and not on an individual tank basis.

Thief hatch and PRV requirements associated with storage vessels that are not affected facilities, or part of a CVS, should be exempt from LDAR requirements (including recordkeeping and reporting), but due to their inclusion in the "fugitive emission components" definition¹⁰² and the language in § 60.5397a(d)(1)(iv)¹⁰³ it seems unclear. Those emissions would have been accounted for in the PTE calculations and are not fugitive emissions.

F. Leak Detection and Repair

The Independent Producers overarching concern is that much more information is required to be documented than is necessary. Many items on the extensive list provide no environmental benefit, or assurance of compliance. Many operators consider Colorado Reg 7 to be overly burdensome, yet it is still more streamlined and efficient than what is currently required in this rule. The following list is inclusive of the recordkeeping and reporting requirements that should be stricken:

- How the leak was repaired
- Time of the survey
- Name/ID of person performing the survey
- Weather and atmospheric conditions
- Deviations from the monitoring plan, or observation path (if they do not create a situation where the survey results are been negatively affected by the modification)
- Type of instrument used to resurvey following a repair is unnecessary

When one asks "what useful information does this provide regulators in regards to compliance assurance?", it is difficult if not impossible to produce an answer that justifies their inclusion, especially considering the associated resource and economic burden. It is the Independent Producers' contention that Colorado Reg. 7 should be the template for fugitive recordkeeping and reporting and request EPA modify these requirements accordingly.

G. Digital Photograph Requirement

Mandating digital photographs, or video records be kept and maintained when using OGI technology does not serve a useful purpose, or in any way ensure compliance with the rule. The EPA has never made the determination that a digital photograph of the analyzer readout is necessary to ensure compliance when using a traditional Method 21 protocol to satisfy LDAR

¹⁰² 40 C.F.R. §60.5430a ("Fugitive Emission Component" definition)

¹⁰³ For *all other* fugitive emission components *not associated with a closed vent system or a controlled storage vessel* under this section, a narrative description of how the fugitive emissions components will be monitored.

requirements, and it subsequently should not be required when using OGI. This is a perfect example of an instance where streamlining could be successfully utilized to remove unnecessary requirements that impart undue burden and financial stress without environmental benefit or additional compliance assurance beyond maintaining records and submitting certified reports that are already required.

H. Observation Path Requirement

The proposed observation path deviation reporting requirements should be eliminated. The EPA has failed to provide adequate proof that this is necessary for compliance assurance, or address industry concerns related to the overly burdensome nature of the tracking, maintenance, and modification of the monitoring plan and/or observation path documents that would be needed to avoid deviation reporting. The CAA authorizes the EPA to promulgate performance standards, but it does not authorize the EPA to force owner/operators to use a single method of complying with those standards. In fact, the CAA mandates that the EPA allow owner/operators the flexibility to determine the most effective compliance method for specific requirements. Adherence to a prescriptive observation path, where even a slight departure creates a potential compliance issue through "deviation" reporting requirements, is unnecessary and in no way correlates to a more effective performance of the survey, or in any way contributes to a reduction of emissions. Facilities are frequently modified and changed through equipment and component additions/removals which creates a perpetual evolution regarding the most effective camera position for successful OGI surveys. Even in situations where the facility equipment has not changed, weather conditions and other environmental factors create scenarios where the survey approach needs to be adjusted in order to achieve the desired result. These on-the-fly adjustments to the monitoring plan and/or observation path should not be considered a reportable deviation. Furthermore, they are absolutely critical to the successful outcome of the survey and applying any sort of negative association by reporting them as "deviations" is counterproductive to the overall intent of the rule. The Independent Producers understand that the EPA has stated that deviations from the monitoring plan are not necessarily deviations from the rule requirements,¹⁰⁴ but we have a difficult time reconciling that when considering the definition of deviation¹⁰⁵ and the very real possibility that regulators will view these reported "deviations" as a failure to meet the requirements of the regulation as the definition suggests. Deviation reporting would also make any Title V facilities subject to OOOOa requirements vulnerable to additional reporting, and possibly enforcement action due to the deviation reporting requirements for major sources.

The EPA has failed to provide a satisfactory explanation for the inclusion of the very tedious and costly recordkeeping and reporting requirements regarding monitoring plans and observation paths, especially considering there are much simpler and more reasonable methods for achieving compliance assurance. The Independent Producers urge the EPA to remove the recordkeeping and reporting requirements regarding deviations and replace them with more flexible performance based standards. These could include requirements for images to be obtained with an unobstructed view (when possible), a requirement that all affected facilities and

¹⁰⁴ 83 Fed. Reg. at 52078

¹⁰⁵ 40 C.F.R. § 60.5430a ("Deviation" definition)

components must be surveyed, a requirement for the operator to position the camera in such a manner that the most accurate image is captured, etc. In the event EPA chooses to maintain the deviation reporting requirements for monitoring plans and observation paths it is imperative that the definition of deviation be modified such that minor changes that are necessary to effectively and satisfactorily to complete the survey are not included.

1. Compliance and Emissions Data Reporting Interface ("CEDRI")

The Independent Producers understand that the CEDRI system is being reconsidered, but we still maintain that after it has been activated that an extended transition period must be utilized to eliminate delays and compliance issues related to system bugs and other integration problems. In addition, it has come to our attention that the few operators that have attempted to use the electronic reporting system have discovered that the process of obtaining facility ID's by first loading all facilities into CEDRI is extremely burdensome with respect to time and resources. This extra step is necessary before data can even begin to be entered into the system. The process of obtaining facility ID's must be simplified before the CEDRI system can be considered an acceptable method of data reporting.

VII. DEFINITION OF MODIFICATION

A. The EPA's Assumptions Associated with Refracturing a Well Does Not Justify Abandoning a Demonstrated Emissions Increase.

The definition of "Modification of a Well Site" proposed by the EPA in the NSPS for the Oil and Natural Gas Sector, 40 CFR 60.5365 a(i)(3), is inconsistent with the definition of "modification" under Section 111 of the CAA both in concept and fact. In the context of the EPA's immediate need to consider staying the fugitive emissions requirements, the impact of the Subpart OOOOa NSPS on modifications is significant. The CAA defines "modification" in the context of Section 111 as:

... any physical change in, or change in the method of operation of, a stationary source which increases the amount of any air pollutant emitted by such source or which results in the emission of any air pollutant not previously emitted.¹⁰⁶

This is not the criteria that the EPA used in defining "modification" in Subpart OOOOa. In Subpart OOOOa, the EPA states:

A "modification" to a well site occurs when:

- (i) A new well is drilled at an existing well site;
- (ii) A well at an existing well site is hydraulically fractured; or

¹⁰⁶ 42 U.S.C.A. § 7411(a)(4).

(iii) A well at an existing well site is hydraulically refractured.¹⁰⁷

The EPA justifies its use of this definition in the Federal Register Notice on Subpart OOOOa by stating:

The EPA believes the addition of a new well or the hydraulically fracturing or refracturing of an existing well will increase emissions from the well site for the following reasons. These events are followed by production from these wells which generate additional emissions at the well sites. Some of these additional emissions will pass through leaking fugitive emission components at the well sites (in addition to the emissions already leaking from those components). Further, it is not uncommon that an increase in production would require additional equipment and, therefore, additional fugitive emission components at the well sites. We also believe that defining "modification" to include these two events, rather than requiring complex case-by-case analysis to determine whether there is emission increase in each event, will ease implementation burden of owners and operators. For the reasons stated above, EPA is finalizing the definition of "modification" of a well site, as proposed.¹⁰⁸

This rationale is generally incorrect as a matter of concept because emissions do not arise from the fracturing of a well, but from production and the equipment to manage these emissions which are in place at the time of the fracturing. In addition, it is factually incorrect to automatically associate an increase in fugitive emissions and, as a result, a "modification" with each instance when a well is refractured. Production from any oil and natural gas well will always decline over time. The graph on page 9 of these Comments shows a typical decline curve for hydraulically fractured wells. Refracturing a well is a normal operational practice to recover some portion of declining production from existing wells. A refractured well will seldom, if ever, bring its production back to its initial volume or operating pressure. If an operator is committed to the expense associated with refracturing a well, part of standard operating practices are to evaluate the equipment on site to ensure that as much gas is recovered as possible. Again – what the EPA views as a pollutant, the industry views as its product. The equipment designed and installed at a particular well is designed to capture the maximum amount of methane or "emissions" that well is anticipated to produce when initially fractured. That same equipment is most likely "oversized" for a refracturing of the well.

The occurrence of a modification under the overarching definition contained in Section 111 requires a calculated increase in the baseline level of actual emissions.¹⁰⁹ Although the CAA defines a "modification" as any physical or operational change causing increased emissions, it does not specify how to calculate "increases" in emissions.¹¹⁰ If the legislative intent of a statutory provision is ambiguous, then a court is entitled to consider "whether the agency's

¹⁰⁷ 81 Fed. Reg. 35900 (June 3, 2016).

¹⁰⁸ 81 Fed. Reg. 35881 (June 3, 2016).

¹⁰⁹ *New York v. U.S. Environmental Protection Agency*, 413 F.3d. 3, 19 (D.C. Cir., 2005).

¹¹⁰ 42 U.S.C.A. §7411(a)(4).

[interpretation] is based on a permissible construction of the statute.¹¹¹ In the event the Agency's application meets that standard, a court will give that interpretation "controlling weight unless [it is] arbitrary, capricious or manifestly contrary to the statute."¹¹² The NSPS does not provide any methodology to support its definition of "modification", it simply assumes that any hydraulic refracture results in increased emissions. Refracturing a low production well is simply does not restore an underperforming well to levels that exceed or even come close to its original production level.

B. The EPA Acknowledged its Logical Inconsistency but has Failed to Justify Such Inconsistency.

In the Reconsideration Rulemaking, the EPA quoted comments previously made by the Independent Producers, not once but twice:

EPA's rationale, that fugitive emissions are a function of the number and types of equipment, and not operating parameters such as pressure and volume, is inconsistent with EPA's justification for what constitutes a 'modification' for an existing well site. EPA assumes that fracturing or refracturing an existing well will increase emissions because of the additional production, i.e., the additional pressure and volume. EPA cannot ignore the laws of physics to the detriment of low production wells in one instance and then 'honor' them in another contexts to eliminate an 'emissions increase' requirement in the traditional definition of 'modification.'¹¹³

The EPA continues to argue that additional equipment will be installed when a well is refractured despite industry's statements to the contrary. In some instances additional equipment may be added but for the most part, equipment is not added. The equipment is designed to the capture the pressures and volumes expected from the initial fracture. The EPA's rational also assumes leaks at the existing equipment. The EPA also discusses other hypothetical instances where a refracture *could* result in an emissions increase.¹¹⁴ The EPA's rational relies on the words "could", "may" and "possibly." This should not be the basis for regulating thousands of existing sources. If the EPA is intent on assuming emissions increases with refracturing a well, which seems heavily reliant on the assumption of leaking components, The EPA should allow operators to conduct a pre-refracture LDAR survey option, which, if demonstrates no leaks, would allow for refracturing that does not trigger a modification.

The EPA also attempts to explain away the inconstancy by citing "support for the petitioners' assertion that equipment counts can vary based on the amount of production at a well site."¹¹⁵ The Independent Producers do not dispute that the number of equipment counts can and does vary based on the amount of production at a well site. That fact does not justify EPA

¹¹¹ *Chevron U.S.A., Inc. v. Natural Res. Def. Council*, 467 U.S. 837, 843 (1984).

¹¹² *Chevron* at 844.

¹¹³ 83 Fed. Reg. 52,067; 83 Fed. Reg. 52,073 (2018).

¹¹⁴ 83 Fed. Reg. 52,073 (2018).

¹¹⁵ 83 Fed. Reg. 52,067 (2018).

ignoring or substantially discounting the impact of decreased production/pressure/volume at low production wells and the impact on emissions. While the Independent Producers appreciate the EPA's efforts to create a Model Low Production Well, as discussed earlier, the assumed equipment counts are high and overestimate emissions from low production wells.

VIII. CONCLUSIONS

The Reconsideration Rulemaking creates opportunities to address issues that were not fully understood or considered in the rush to complete Subpart OOOOa under the political pressures of the previous Administration. The Independent Producers support this essential action. In particular, the Independent Producers support the following positive changes:

Changing the large production well fugitive emissions program to an annual cycle. The EPA's initial actions in Subpart OOOOa were based on inaccurate assumptions. As the API has identified, both the initial failure rate and the time for subsequent actions were incorrect and drove the EPA to overvalue a semi-annual cycle. The revisions to an annual cycle is an appropriate step.

Addressing the requirements to use a Professional Engineer to certify certain actions and the revisions to the provisions on pneumatic pumps are important steps forward but both need additional clarification and modifications.

However, as stated above, the Independent Producers believe that additional changes are essential to fully address the regulatory framework in Subparts OOOO and OOOOa as they affect America's oil and natural gas productions. These include:

The resurrection of a distinction for low production wells is a key and essential part of the new proposal. However, as the Independent Producers discuss above, the proposal falls short of being a workable structure. No specific requirements for low production wells should be required unless and until the EPA obtains specific information on low production well emissions and determines regulations are necessary and that cost-effective regulations can be created.

The EPA's proposal on storage vessels needs to be significantly revised or eliminated. The Agency's proposal to prohibit averaging of throughput across tank batteries inappropriately ignores the relevant process unit and is inconsistent with recent consent decrees related to the design and operation of vapor control systems on storage tanks/vessels. The EPA's concern about the amount of storage vessels subject to Subpart OOOOa is overstated and unfounded. Its proposal to calculate individual tank emissions based upon throughput to each individual tank is technically flawed and overly burdensome. The EPA's proposed revisions to what constitutes "legally and practically enforceable limits" is unnecessary and arbitrarily interferes with the Clean Air Act's cooperative federalism where the states are to take lead on implementation.

The Independent Producers support the AMEL options in the proposal to use modeling to test technologies in a controlled test environment, and to allow manufactures/vendors to apply for approvals. However, the EPA should allow for basin-wide approvals of emerging technology for use in complying with the LDAR requirements in the rule.

The EPA should recognize the approved state LDAR programs as wholly ambivalent to Subpart 0000's LDAR program and fully delegate the implementation of the LDAR monitoring provisions to these respective states. Alternatively, the EPA could require the fugitive emissions component definition from Subpart 0000a to be used when following an alternative approved state program, but the EPA should not require a duplicative administrative burden; to do so would be an undue burden with no corresponding environmental benefit.

The Independent Producers believe that further changes to limit excessive recordkeeping and reporting need to be made – changes to prevent unnecessary burdens that have no environmental benefit – and the definition of "modification" should be refined to be consistent with the intent of the CAA.

The Independent Producers submit these Comments collectively. The Independent Producers also endorse those Comments that are submitted separately by member organizations. Additionally, the Independent Producers support the Comments and proposals submitted by the API and commend its information supporting an annual fugitive emissions program for large production wells to the EPA.

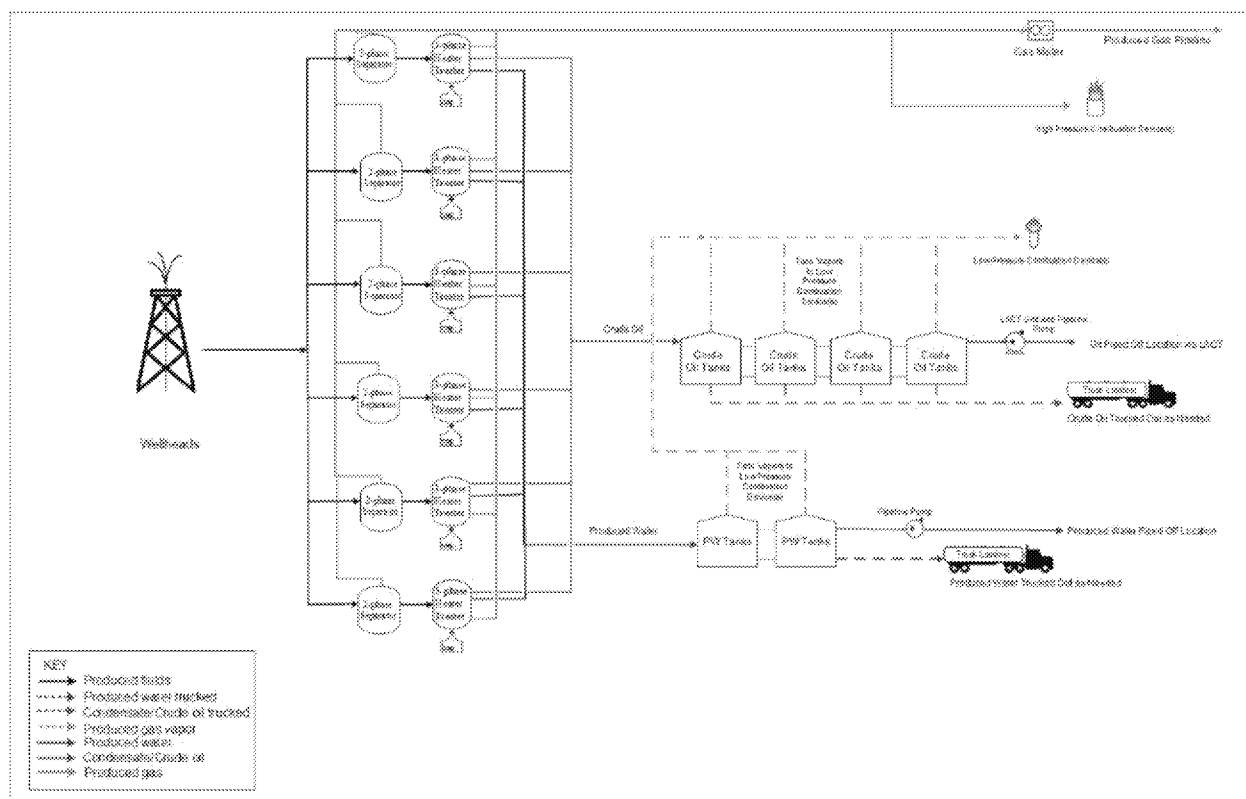

If there are questions regarding these Comments, please contact me, counsel for the Independent Producers.

Respectfully submitted,

EPA Proposes Updates to Air Regulations for Oil and Gas to Remove Redundant Requirements and Reduce Burden

Contact Information:

EPA Press Office (press@epa.gov)

WASHINGTON (August 29, 2019) –The U.S. Environmental Protection Agency (EPA) proposed updates to the prior administration’s national standards for the oil and natural gas industry. The proposal would remove regulatory duplication and save the industry millions of dollars in compliance costs each year – while maintaining health and environmental regulations on oil and gas sources that the agency considers appropriate.

Today’s proposal is the result of EPA’s review of the 2016 New Source Performance Standards (NSPS) for the oil and natural gas industry, which was conducted in response to President Trump’s Executive Order 13783 - Promoting Energy Independence and Economic Growth. That order directs agencies to review existing regulations that potentially “burden the development or use of domestically produced energy resources,” including oil and natural gas. EPA’s regulatory impact analysis estimates that the proposed amendments would save the oil and natural gas industry \$17-\$19 million a year, for a total of \$97-\$123 million from 2019 through 2025.

“EPA’s proposal delivers on President Trump’s executive order and removes unnecessary and duplicative regulatory burdens from the oil and gas industry,” **said EPA Administrator Andrew Wheeler**. “The Trump Administration recognizes that methane is valuable, and the industry has an incentive to minimize leaks and maximize its use. Since 1990, natural gas production in the United States has almost doubled while methane emissions across the natural gas industry have fallen by nearly 15%. Our regulations should not stifle this innovation and progress.”

EPA is co-proposing two actions, both of which would remove unnecessary regulatory duplication in the 2016 rule. In its primary proposal, the agency would remove sources in the transmission and storage segment of the oil and gas industry from regulation. These sources include transmission compressor stations, pneumatic controllers, and underground storage vessels. The agency is proposing that the addition of these sources to the 2016 rule was not appropriate, noting that the agency did not make a separate finding to determine that the emissions from the transmission and storage segment of the industry causes or significantly contributes to air pollution that may endanger public health or welfare.

The primary proposal also would rescind emissions limits for methane, from the production and processing segments of the industry but would keep emissions limits for ozone-forming volatile organic compounds

(VOCs). These sources include well completions, pneumatic pumps, pneumatic controllers, gathering and boosting compressors, natural gas processing plants and storage tanks. The controls to reduce VOCs emissions also reduce methane at the same time, so separate methane limitations for that segment of the industry are redundant.

In an alternative proposal, EPA would rescind the methane emissions limitations without removing from regulation any sources from the transmission and storage segment of the industry.

The agency also is seeking comment on alternative interpretations of EPA's legal authority to regulate pollutants under section 111(b)(1)(A) of the Clean Air Act.

This proposal is in addition to a September 2018 technical action that proposed targeted improvements to help streamline implementation, reduce duplication of EPA and state requirements, and significantly decrease unnecessary burdens on domestic energy producers. EPA is currently reviewing comments received on that technical package and expects to issue a final rule in the upcoming months.

EPA will take comment on the proposal for 60 days after it is published in the Federal Register and will hold a public hearing. Details of the hearing will be announced shortly.
